A NOTE ON PAUESIA KONOI (WATANABE) (HYMENOPTERA : APHIDIIDAE)

By CHIHISA WATANABE and HAJIMU TAKADA

As a supplement to the original description of Aphidius konoi Watanabe a brief note will be given below.

**Pauesia konoi** (Watanabe)

*Aphidius konoi* Watanabe, Ins. Mats. 15: 106, i, 1941.

Specimens examined: 4♂♀ (types of *Aphidius konoi*); 5♀♀, 1♂, 23-v-62, Yuni, Hokkaido, Watanabe leg.; 30♀♀, 20♂♂, 24-v-62, Yuni, Hokkaido, Watanabe leg.; 13♀♀, 7♂♂, 18-v-63, 4♀♀, 2♂♂, 25-v-63, Naganuma, Hokkaido, Takada leg. All specimens were reared from *Cinara longipennis* (Matsumura) living in *Abies sashalinensis*.

♀. The female of this species was not previously known: it agrees closely with the original description of the male, apart from usual sexual differences, except as follows:—

Antennae with 27–29 segments [27 (15♀♀), 28 (33), 29 (2)], being 2.8–4.4 mm. in length. Petiole more widened towards the apex than in the male. Length of body, 4.2–5.8 mm.

♂. In the male specimens examined the antennae with 29–31 segments [29 (6♀♀), 30 (17), 31 (4)], being 3.5–4.8 mm. in length. Length of body, 3.1–4.7 mm.

As the senior author already pointed out in 1941 the present species is closely related to *Pauesia grossa* (Fahringer, 1937), a parasite of *Todolachnus abieticola* (Cholodkovsky) in Europe (Austria and Czechoslovakia). Having compared the specimens examined with Starý’s redescription of *P. grossa* with figures (Acta Faun. Ent. Mus. Nat. Pragae 6: 13–14, figs. 1, 22, 45 & 50, 1960), we have corroborated that the two forms are different full species. The present species is immediately distinguishable therefrom by the following aspects:—

1. Head black, darker than in *glossa*. 2. Scape and pedicel black. 3. Prothorax black. Mesoscutum wholly black, being not yellow brown with a dark longitudinal spot on each lobe as in *glossa*. 4. Abdomen black; 2nd tergite with a broad brown band at base. 5. Metacarp shorter than pterostigma. 6. Central, pentagonal areola of propodeum smaller than in *glossa*, the rami of central carina not reaching about spiracles. 7. Petiole stouter than in *glossa*. The female genitalia of this species, however, are very similar to the figure of those of *glossa* drawn by Starý (1960), and no special differences can be found between them.
