EXAMPLES OF NON MINIMAL POINTS ON RIEMANN SURFACES OF PLANER CHARACTER.

by

Zenjiro KURAMOCHI

The Martin's topologies on Riemann surfaces have been discussed by many authors and some examples of boundary points have been given. Prof. M. BreLOT¹⁾ gave a domain D in the z -plane such that there exist two sequences $q_{i,n}$ ($n=1, 2, \dots$) ($i=1, 2$) in D tending to q_i as $n \rightarrow \infty$, $q_2 \neq q_1$ which determine the same K -Martin's boundary point to show that the K -Martin's topology is not necessarily finer than the euclidean topology. Also we constructed examples in the z -plane to show that N -Martin's topology is neither finer than the K -Martin's topology and K -Martin's topology is nor finer than the N -Martin's topology²⁾. As for non minimal points, R. S. Martin presented an example of K -non minimal point in 3-dim. euclidean space³⁾ and we gave a Riemann surface of infinite genus contained in the class H.2.P.⁴⁾ in which there exists atleast one K - and N -non minimal point⁵⁾. But the examples of non minimal point in a domain of planer character have not been given. Mr. Ikegami proposed the following problem:

Does there exist a non minimal point on Riemann surfaces of planer character?

The purpose of the present paper is to discuss the relation between the classes of positive harmonic functions of some classes in R and R' when R varies to R' and also is to give examples of non minimal points of Riemann surfaces of planer character.

Lemma 1. *(An estimation of the harmonic measure of an arc on*

a curve). Let C be a unit circle, $C: |z| < 1$ and let S' be a straight in C with endpoints, A' and B' such that $S': \operatorname{Im} z = 0, a' \leq \operatorname{Re} z \leq b'$, where $a' \leq -\frac{1}{3}$ and $b' \geq \frac{1}{3}$. Let Γ be a circle in $C: |z| = \frac{1}{12}$. Let T be a straight on S' such that $T: \operatorname{Im} z = 0, -\delta \leq \operatorname{Re} z \leq \delta$. Suppose $\delta \leq \frac{\pi}{18}$. Then $w(T, z)$, H.M. (harmonic measure) of T with respect to $C-S'$ satisfies

$$w(T, z) \leq \frac{0.664}{\pi} |\sin \theta|, \quad z = \frac{e^{i\theta}}{12}.$$

Proof. Let S be a straight on the real axis, $S: \operatorname{Im} z = 0, -\frac{1}{3} \leq \operatorname{Re} z \leq \frac{1}{3}$. Then $S' \supset S$. Let Ω_z be the complementary set of S in the z -plane. By brief consideration, when δ is sufficiently small, we see $w^*(T, z)$ has almost same value as $w(T, z)$ on Γ , where $w^*(T, z)$ is H.M. of T with respect to Ω_z . Clearly $w(T, z) \leq w^*(T, z)$. Map Ω_z by $w = \frac{z + \frac{1}{3}}{z - \frac{1}{3}}$ onto Ω_w , where Ω_w is the complementary domain of the straight: $\operatorname{Im} w = 0, 0 \leq \operatorname{Re} w \leq \infty$. Then $\Gamma \rightarrow$ a circle: $\left| w - \frac{6}{5} \right| < \frac{7}{15}$.

Fig. 1.

Map Ω_w by $\zeta = \sqrt{w}$ onto $\Omega_\zeta: \operatorname{Im} \zeta > 0$. Also map Ω_ζ by $\xi = \frac{\zeta - i}{\zeta + i}$ onto $|\xi| < 1$. Then T is mapped onto $T_1 + T_2$ and Γ is mapped onto $\Gamma_1 + \Gamma_2$ respectively, where $T_1: e^{i(-\frac{\pi}{2} + \epsilon)}$ for $-\frac{3\delta}{2} \leq \epsilon \leq \frac{3\delta}{2}$, $T_2: e^{i(\frac{\pi}{2} + \epsilon)}$ for $-\frac{3\delta}{2} \leq \epsilon \leq \frac{3\delta}{2}$, Γ_1 and Γ_2 are curves in the lower and upper semicircles respectively. Let $w^*(T_i, \xi)$ be H.M. of T_i . Then $w(T, z) \leq \sum_{i=1}^2 w^*(T_i, \xi)$. We con-

Fig. 2.

sider $w^*(T_1, \xi)$ on Γ_1 . Then $w(T, \xi) \leq \frac{\theta - \frac{3}{2}\delta}{\pi - \frac{3}{2}\delta}$,

where

$$\Theta = \arg \frac{e^{i(-\frac{\pi}{2} + \frac{3\delta}{2})} - \xi}{e^{i(-\frac{\pi}{2} - \frac{3\delta}{2})} - \xi}. \quad (1)$$

We denote by p_ξ , the point ξ on Γ_1 . We shall express p_ξ by z . Let $p_z = \frac{e^{i\theta}}{12}$ on Γ in the upper half plane. Then p_w , the image of p_z is given by Fig. 3 as

$$p_w = re^{i\varphi},$$

Fig. 3.

$$\text{where } r = \sqrt{\frac{17+8\cos\theta}{17-8\cos\theta}} \text{ and}$$

$$\varphi = \cos^{-1} \frac{15}{\sqrt{17-8\cos\theta}}.$$

Let p_ζ be the image of p_w . Then $\rho_\zeta = \rho e^{i\phi}$, where $\rho = r^{\frac{1}{2}}$, $\phi = \frac{\varphi}{2}$.

$$\text{Let } p_\xi \text{ be the image of } p_\zeta. \text{ Then } p_\xi = Re^{i\Phi}, \quad (2)$$

$$\text{where } R = \sqrt{\frac{1+\rho^2-2\rho\sin\phi}{1+\rho^2+2\rho\sin\phi}}, \quad \sin\Phi = \frac{2\rho\cos\varphi}{\sqrt{1+\rho^4+2\rho^2\cos 2\varphi}} \geq 0, \quad (3)$$

$$\cos\Phi = \frac{\rho^2-1}{\sqrt{1+\rho^4+2\rho^2\cos 2\varphi}}.$$

By the shape of Γ_1 we see that R is minimal, when $\Phi = -\frac{\pi}{2}$, i.e. $\theta = \frac{\pi}{2}$,

$$\rho = 1, \quad \cos\varphi = \frac{15}{17}, \quad \sin\phi = \frac{1}{\sqrt{17}} \quad \text{and} \quad R = \frac{\sqrt{17}-1}{4}. \quad (4)$$

$$\text{Now by (1) } \Theta = \tan^{-1} \frac{2R \sin\Phi \sin \frac{3\delta}{2} + \sin 3\delta}{R^2 + 2R \sin \cos \frac{3\delta}{2} + \cos 3\delta}. \quad \text{Put } \Psi = \Theta - \frac{3\delta}{2}. \quad \text{Then}$$

$$\tan \Psi = \frac{(1-R^2) \sin \frac{3}{2}\delta}{(1+R^2) \cos \frac{3}{2}\delta + 2R \sin \Phi + \cos \frac{3}{2}\delta} \leq \frac{(1-R^2) \sin \frac{3}{2}\delta}{(2+R^2) \cos \frac{3}{2}\delta}. \quad \text{We have by}$$

$$(2) \text{ and } (3) \quad (1-R^2) = \frac{2 \sin \theta}{(17^2 - 8^2 \cos^2 \theta)^{\frac{1}{2}} ((17^2 - 8^2 \cos^2 \theta) + 15)^{\frac{1}{2}}} \leq \frac{\sqrt{2}}{5} \sin \theta. \quad \text{Hence}$$

by $\delta \leq \frac{\pi}{18}$ and by (4)

$$\begin{aligned}
\Psi \leq \tan \Psi &\leq \frac{2 \sin \theta \sin \frac{3}{2} \delta}{15(2+R^2)} \leq \frac{8\sqrt{2} \sin \theta \sin \frac{3}{2} \delta}{15(25-\sqrt{17}) \cos \frac{3}{2} \delta} \\
&\leq \frac{12\sqrt{2} \delta \sin \theta}{15(25-\sqrt{17}) \cos \frac{\pi}{12}} < 0.28 \delta \sin \theta.
\end{aligned} \quad (5)$$

Hence $w^*(T, \xi) \leq \frac{0.332}{\pi} \delta \sin \theta$, $z = \frac{e^{i\theta}}{12}$ on Γ_1 . Next clearly

$w(T_2, z) \leq w^*(T, \xi)$ on Γ_1 , whence

$$w(T, z) \leq \frac{0.664 \delta \sin \theta}{\pi}, \quad z = \frac{e^{i\theta}}{12}, \quad \pi \geq \theta \geq 0. \quad (6)$$

Similar result is obtained for $\pi \leq \theta \leq 2\pi$. Thus we have Lemma 1.

Lemma 2. (An estimation of harmonic measure of an arc). Let Ω be the semicircle: $|z| \leq 1, \operatorname{Im} z \geq 0$. Let S be an arc on $|z|=1$ with endpoints A and B , $A = 1 - \sqrt{2} + 2\sqrt{2} \sqrt{\sqrt{2}-1}i$ and $B = \sqrt{2} - 1 + 2\sqrt{2} \sqrt{\sqrt{2}-1}i$. Let Γ be a semicircle: $z = \frac{e^{i\theta}}{2}$, $0 \leq \theta \leq \pi$. Let $w(S, z)$ be H.M. of S with respect to Ω . Then

$$w(S, z) \geq \frac{2}{3\pi} \min \left(\frac{\pi}{12}, \frac{24}{25} \sin \theta \right) \quad \text{on } \Gamma.$$

Map Ω by $w = \frac{z+1}{1-z}$ onto Ω_w , map Ω_w by $\zeta = w^2$ onto Ω_ζ and map Ω_ζ by $\xi = \frac{\zeta-i}{\zeta+i}$ onto $|\xi| < 1$. Then A and B are mapped onto $e^{\frac{3}{4}\pi i}$ and $e^{\frac{\pi}{4}i}$ of ξ -plane respectively. Let $p = \frac{e^{i\theta}}{2}$: $\pi \geq \theta \geq 0$ and let p_w, p_ζ and p_ξ be the images of p in w, ζ and ξ -plane. Then we have $p_w = re^{i\varphi}$, where

$$\cos \varphi = \frac{3}{\sqrt{25-16 \cos^2 \theta}}, \quad r = \sqrt{\frac{5+4 \cos \theta}{5-4 \cos \theta}},$$

$$p_\zeta = \rho e^{i\phi},$$

where $\rho = r^2$ and $\phi = 2\varphi$, $\sin \phi = \frac{24 \sin \theta}{25-16 \cos^2 \theta} \geq \frac{24 \sin \theta}{25}$ and $\frac{1}{9} \leq \rho \leq 9$. (7)

$$p_\xi = R e^{i\Phi},$$

where $R = \sqrt{\frac{1+\rho^2-2\rho \sin \phi}{1+\rho^2+2\rho \sin \phi}}$, $\sin \Phi = \frac{2 \cos \varphi}{\sqrt{1+\rho^4+2\rho^2 \cos^2 \varphi}} \geq 0$ (8)

Fig. 4.

Fig. 5.

and R is minimal, when $\theta=0$, i.e. $r=1$, $\rho=1$, $\sin \phi = \frac{24}{25}$ and $R = \frac{1}{7}$.

Put $\Theta = \arg \frac{e^{\frac{3\pi}{4}i} - p_\xi}{e^{\frac{\pi}{4}i} - p_\xi}$. Then by (8) $\Theta = \left(1 + \frac{1-R^2}{R^2 - \sqrt{2} R \sin \Phi}\right)$. On the other hand, we see easily

$$\tan\left(\frac{\pi}{4} + \frac{s}{4}\right) \leq 1+s \text{ for } 0 \leq s \leq \frac{\pi}{3}, \text{ whence}$$

$$\Theta \geq \frac{\pi}{4} + \min\left(\frac{\pi}{12}, \frac{1-R^2}{4(R^2 - \sqrt{2} R \sin \Phi)}\right).$$

By (8) and (7) $(1-R^2) = \frac{4\rho \sin \phi}{1+\rho^2+2\rho \sin \phi} \geq \frac{4\rho \sin \phi}{(1+\rho)^2} \geq \frac{48}{25} \sin \theta$, because $\frac{4\rho}{1+\rho^2} \leq 1$ for $\frac{1}{9} \leq \rho \leq 9$.

Also by (8) $\Theta \geq \frac{\pi}{4} + \min\left(\frac{\pi}{12}, \frac{24}{25} \sin \theta\right)$. Hence

$$w(T, z) \geq \frac{\Theta - \frac{\pi}{4}}{\frac{3}{4}\pi} = \frac{4}{3\pi} \min\left(\frac{\pi}{12}, \frac{24 \sin \theta}{25}\right), \quad z = \frac{e^{i\theta}}{2}.$$

Lemma 3. Let C, C', C'' and C''' be circles, $C: |z| < 1$, $C': |z| < \frac{1}{3}$, $C'': |z| < \frac{1}{6}$, $C''': |z| < \frac{1}{12}$. Let Γ_1 and Γ_2 be straight segments on the real axis such that $\Gamma_1: a \leq \operatorname{Re} z \leq -\delta$, $\Gamma_2: -\delta \leq \operatorname{Re} z \leq b$, where $a \leq -\frac{1}{3}$, $b \geq -\frac{1}{3}$ and let γ be a closed set in $C - C'$. Let $T: \operatorname{Im} z = 0$, $-\delta \leq \operatorname{Re} z \leq \delta$ and let $U(z)$ be a positive harmonic function in $C' - \Gamma_1 - \Gamma_2$ vanishing on $\Gamma_1 + \Gamma_2$ and let $w(T, z)$ be H.M. of T with respect to $C - T$. Then there exists a constant M such that

$$M\delta U(z) \geq \left(\sup_{z \in \partial C'''} U(z)\right) w(T, z) \text{ on } \partial C'''.$$

Let $F = F_1 + F_2$ and $F_1: \frac{e^{i\theta}}{6}, \frac{3\pi}{4} \leq \theta \leq \frac{\pi}{4}, F_2: \frac{e^{i\theta}}{6}, \frac{7\pi}{4} \leq \theta \leq \frac{5\pi}{4}$. Map $C' - \Gamma_1 - \Gamma_2$ onto $|\xi| < 1$ so that $z=0 \rightarrow \xi=0$ and let Γ_ξ, F_ξ and C'''_ξ be the images of $\Gamma_1 + \Gamma_2, F_1 + F_2$ and C''' respectively. Let CF_ξ

Fig. 6.

be the complementary periphery of Γ_ξ . Since $\text{dist}(C\Gamma_\xi, F_\xi) > 0$, there exists a const. K_1 such that $\frac{1-r^2}{1-2r\cos(\theta-\varphi)+r^2} \geq K_1$ for $\xi \in F_\xi$, $\xi = re^{i\theta}$, whence $\min_{z \in F_1+F_2} U(z) = \min_{\xi \in F_\xi} U(\xi) \geq K_1 U_\xi(0)$. Also since $\text{dist}(\partial C_\xi''', C\Gamma_\xi) = 0$, there exists a const. K such that $\frac{1}{1-2r\cos(\theta-\varphi)+r^2} \leq K_2$ for $\xi \in \partial C_\xi'''$, whence $\sup_{\xi \in \partial C_\xi'''} U(\xi) \leq K_2(1-r^2)U_\xi(0)$. Hence putting $M' = \frac{K_1}{K_2}$ we have $M' \min_{z \in F_1+F_2} U(z) \geq \sup_{z \in \partial C_\xi'''} U(z)$. Put $A = \sup_{z \in \partial C_\xi'''} U(z)$ and $B = \min_{z \in F_1+F_2} U(z)$. Then $B \geq \frac{A}{M'}$. Clearly $U(z) \geq Bw(F, z)$ in C'' and by Lemma 2 $U(z) \geq BC_2 \sin \theta$ for $z = \frac{e^{i\theta}}{12}$, where $w(F, z)$ is H.M. of F_1+F_2 with respect to $C'' - \Gamma_1 - \Gamma_2 - T$ and $C_2 = \frac{4}{3\pi} \min\left(\frac{\pi}{12}, \frac{24}{25}\right)$. By Lemma 1, $w(T, z) \leq C_1 \delta \sin \theta$ for $z = \frac{e^{i\theta}}{12}$, where $w(T, z)$ is H.M. of T with respect to C and $C_1 = \frac{0.664}{\pi}$. Hence $U(z) \geq BC_2 \sin \theta \geq BC_2 \frac{w(T, z)}{C_1 \delta} \geq \frac{AC_2}{M'C_1 \delta} w(T, z) \frac{C_2}{M'C_1 \delta} (\sup_{z \in \partial C_\xi'''} U(z)) w(T, z)$ for $z = \frac{e^{i\theta}}{12}$. Put $M = \frac{M'C_1}{C_2}$. Then $M \delta U(z) \geq (\sup_{z \in \partial C_\xi'''} U(z)) w(T, z)$, for $z = \frac{e^{i\theta}}{12}$.

Let R be a Riemann surface with positive boundary and let $\{R_n\}$ be its exhaustion with compact relative boundary ∂R_n ($n=1, 2, \dots$). Let G be a subdomain (in this paper we suppose the relative boundary ∂G of G consists of enumerably infinite number of analytic curves clustering nowhere in R). Let P.H.(G) and $\dot{\text{P.H.}}(G)$ be the sets of positive harmonic function (is abbreviated to P.H.) in G and P.H. in G vanishing on ∂G . Let $U(z) \in \dot{\text{P.H.}}(G)$ and let $U_n(z)$ be the least positive harmonic function (is abbreviated to L.P.H.) in $R - (G \cap (R - R_n))$ such that $U_n(z) = U(z)$ on $G \cap (R - R_n)$. Then $U_n(z) \uparrow$ a limit function denoted by $EU(z)$. Let $V(z) \in \text{P.H.}(R)$ and let $V_n(z)$ be the L.P.H. in $G - (R - R_n)$ such that $V_n(z) \geq V(z)$ on $G \cap (R - R_n)$. Then $V_n(z) \downarrow IV(z)$. Then we have the following

Theorem 1. a). If $EU(z) < \infty$, $IEU(z) = U(z)$ ⁶⁾.

b). Let $V(z) \in \text{P.H.}(R)$. Let D be a domain in R and let $V_D(z)$ be L.P.H. in $R - D$ such that $V_D(z) = V(z)$ on D . Let $U(z) \in \dot{\text{P.H.}}(G)$ and $EU(z) < \infty$. Then $\lim_n \sup_{z \in G \cap (R - R_n)} EU(z) = 0$.

6) Z. KURAMOCHI: Relations between harmonic dimensions. Proc. Japan Acad. 30, 576-580 (1954).

This means $EU(z)$ tends to zero as $z \rightarrow B \cap CG$ ($B \cap CG$ means the ideal boundary determined by a domain CG) except a set of harmonic measure zero).

Let $V(z) \in P.H.(R)$. If $\lim_n V_{G \cap (R-R_n)}(z) = V(z)$, we say $V(z) = 0$ a.e. on $(B \cap CG)$. Next let $w(z)$ be L.P.H. in G such that $w(z) \geq V(z)$ on ∂G . Let $\tilde{w}_n(z)$ be L.P.H. in $R - (G \cap (R - R_n))$ such that $\tilde{w}_n(z) = w(z)$ on $G \cap (R - R_n)$. If $\lim_n \tilde{w}_n(z) = 0$, we say $V(z)$ is regular relative to G . Then we have

c). Let $V(z) \in P.H.(R)$. Suppose $V(z) = 0$ a.e. on $CG \cap B$ and $V(z)$ is regular relative to G . Then if $IV(z) > 0$, then $EIV(z) = V(z)$.

d). If $EU(z) < \infty$, then $EU(z)$ is regular relative to G .

e). Let $V(z) \in P.H.(R)$. If there exists at least one $U(z)^n$ in $P.H.(G)$ such that $V(z) \leq EU(z)$ and if $IV(z) > 0$, then $EIV(z) = V(z)$.

Proof of a) is given in the previous paper⁸⁾.

Proof of b). Let $\check{V}_{n,n+i}(z)$ be a P.H. in $R_n + ((R_{n+i} - R_n) \cap G)$ such that $\check{V}_{n,n+i}(z) = EU(z)$ on $\partial R_{n+i} \cap G$, $\check{V}_{n,n+i}(z) = 0$ on $(\partial R_n - G) + (\partial G \cap (R_{n+i} - R_n))$. Let $\hat{V}_{n,n+i}(z)$ be a P.H. in $R_n + ((R_{n+i} - R_n) \cap G)$ such that $\hat{V}_{n,n+i}(z) = EU(z)$ on $(\partial R_n \cap CG) + (\partial G \cap (R_{n+i} - R_n))$ and $\hat{V}_{n,n+i}(z) = 0$ on $\partial R_{n+i} \cap G$. Then

$$\hat{V}_{n,n+i}(z) + \check{V}_{n,n+i}(z) = EU(z).$$

where $G_{\sum_{n_0}^{\infty} r_n}(z, p)$ is the Green's function of R' , because $R'' - \sum_{n_0}^{\infty} r_n = R + \sum_{1}^{n_0-1} r_n = R'$.

In the following we suppose K -Martin's topologies are defined in R'' and R' by using $K''(z, p)$ and $K'(z, p)$, where $K''(z, p) = \frac{G''(z, p)}{G''(z_0, p)}$, $K'(z, p) = \frac{G'(z, p)}{G'(z_0, p)}$ and z_0 is a fixed point in $R - \sum C_n$. Put $\bar{R}' = R' + B'$ and $\bar{R}'' = R'' + B''$, where B' and B'' are ideal boundaries of R' and R'' respectively.

Let $\{p_i\}$ be a sequence determining a point $p' \in B'$ such that $p_i \notin \sum C_n$. Then by (10)

$$\frac{1}{2} K''(z, p_i) \leq K'(z, p_i) \leq 2K''(z, p_i) \quad \text{for } z \notin \sum C_n''. \quad (11)$$

Then we can find a subsequence $\{p'_i\}$ of $\{p_i\}$ such that $\{p'_i\}$ converges to a point $p'' \notin B''$. Then

$$\frac{1}{2} K''(z, p'') \leq K'(z, p') \leq 2K''(z, p'') \quad \text{for } z \notin \sum C_n', \quad (12)$$

Proof of d). Let $U(z) \in \dot{P}.H.(G)$ and $EU(z) < \infty$. Let $w_n(z)$ be a P.H. in $G \cap R_n$ such that $w_n(z) = 0$ on $\partial R_n \cap G$, $w_n(z) = EU(z)$ on $\partial G \cap R_n$. Then $w_n(z) + U(z) \leq EU(z)$ on $(\partial G \cap R_n) + (\partial R_n \cap G)$. Let $n \rightarrow \infty$. Then $\lim_n w_n(z) = w(z)$ is L.P.H. in G such that $w(z) \geq EU(z)$ on ∂G and $w(z) + U(z) \leq EU(z)$ in G . Let $\tilde{w}_{n,n+i}(z)$ be a P.H. in $R_{n+i} - (G \cap (R_{n+i} - R_n))$ such that $\tilde{w}_{n,n+i}(z) = w(z)$ on $\partial R_n \cap G$, $\tilde{w}_{n,n+i}(z) = 0$ on $(\partial G \cap (R_{n+i} - R_n)) + \partial R_{n+i} - G$. Let $T_{n,n+i}(z)$ be a P.H. in $R_{n+i} - (G \cap (R_{n+i} - R_n))$ such that $T_{n,n+i}(z) = U(z)$ on $\partial R_n \cap G$, $T_{n,n+i}(z) = 0$ on $(\partial G \cap (R_{n+i} - R_n)) + (\partial R_{n+i} - G)$. Then $\tilde{w}_{n,n+i}(z) + T_{n,n+i}(z) \leq w(z) + U(z)$ on $(\partial R_{n+i} \cap G) + (\partial G \cap (R_{n+i} - R_n))$, $\tilde{w}_{n,n+i}(z) + T_{n,n+i}(z) \leq EU(z)$. Let $i \rightarrow \infty$. Then $\tilde{w}_{n,n+i}(z) \rightarrow \tilde{w}_n(z)$ and $T_{n,n+i}(z) \rightarrow T_n(z)$. Now $T_n(z)$ is L.P.H. in $R - ((R - R_n) \cap G)$ such that $T_n(z) \geq U(z)$ on $\partial G \cap R_n$, whence $\lim_n T_n(z) = EU(z)$. Also $\tilde{w}_n(z)$ is L.P.H. in $R - ((R - R_n) \cap G)$ such that $\tilde{w}_n(z) \leq w(z)$ on $\partial G \cap R_n$. Let $n \rightarrow \infty$. Then $\lim_n \tilde{w}_n(z) + EU(z) \leq EU(z)$ and $\lim_n \tilde{w}_n(z) = 0$. Whence $EU(z)$ is regular relative to G .

Proof of e). By $V(z) \leq EU(z)$, $\lim_n V_{CG \cap (R - R_n)}(z) = 0$ by (b). Clearly

$$\lim_n V_{CG \cap (R - R_n)}(z) + \lim_n V_{G \cap (R - R_n)}(z) \geq \lim_n V_{R - R_n}(z) = V(z) \geq \lim_n V_{G \cap (R - R_n)}(z).$$

Hence $V(z) = \lim_n V_{G \cap (R - R_n)}(z)$, i.e. $V(z) = 0$ a.e. on $CG \cap B$. By $V(z) \leq EU(z)$ and by (d) $V(z)$ is regular relative to G . Hence by (c) we have (e).

We denote by $\dot{P}.H.(R)$ the subclass of $V(z)$ in $P.H.(R)$ such that $V(z) = 0$ a.e. on $CG \cap B$, $V(z)$ is regular relative to G and $IV(z) > 0$ and let $\dot{P}.H.(G)$ be the subclass of $U(z)$ in $P.H.(G)$ such that $EU(z) < \infty$. Then by a) and c) we have at once the following

Corollary. $\dot{P}.H.(R)$ and $\dot{P}.H.(G)$ are isomorphic with respect to E and I operations.

Let $G \supset G'$ be subdomains and let Γ and Γ' be sets consisting of arcs in ∂G and $\partial G'$ respectively, where $\Gamma' \subset \Gamma$. Let $\dot{P}.H.^{\Gamma}(G)$ be the set of P.H.'s $U(z)$ in G such that $U(z) = 0$ on $\partial G - \Gamma$, $\frac{\partial}{\partial n} U(z) = 0$ on Γ . Let $U_n(z)$ be L.P.H. in G' such that $U_n(z) \geq U(z)$ on $G' \cap (R - R_n)$, $\frac{\partial}{\partial n} U_n(z) = 0$ on Γ . Put $\overset{N}{EU}(z) = \lim_n U_n(z)$. Similarly we define $\overset{N}{IV}(z)$ from $V(z)$ in $\dot{P}.H.^{\Gamma}(G)$. Let $\hat{G}$ be the symmetric surface of G with respect to ∂G and identify Γ and $\hat{\Gamma}$, the symmetric image of Γ . Then we have a doubled surface $G + \hat{G}$ which has its relative boundary $(\partial G - \Gamma) + (\partial \hat{G} - \hat{\Gamma})$, where $\hat{G}$ is the symmetric image of G . Let $\hat{z}$ be the symmetric image of z and put $U(\hat{z}) = U(z)$ in $\hat{G}$. Then $\tilde{U}(z) (= U(z) \text{ in } G \text{ and } = U(\hat{z}) \text{ in } \hat{G}) \in \dot{P}.H.(G + \hat{G})$. Let $\hat{G}'$ to the symmetric image

of G' with respect to ∂G and identify I' and $\hat{I}'$. Then we have $(G + \hat{G}')$. Now $(G' + \hat{G}')$ is contained in $(G + \hat{G})$ by $G' \subset G$ and $I' \subset I$, $(G' + \hat{G}')$ has relative boundary $(\partial G' - I' + \partial \hat{G}' - \hat{I}')$ in $(G + \hat{G})$. Hence Theorem 1 is valid for $\overset{N}{E}$ and $\overset{N}{I}$. To avoid repetition we do not state the Theorem 1 for $\overset{N}{E}$ and $\overset{N}{I}$ and we denote it simply by N -Theorem 1.

Lemma 4. *Let R^* be a Riemann surface with positive boundary. Let R be a subsurface in R^* and let $\sum_{n=1}^{n_0} \gamma_n$ be a compact set on ∂R , which is compact in R^* . Put $R' = R + \sum_{n=1}^{n_0} \gamma_n$. Then $\dot{P}.H.(R)$ and $\dot{P}.H.(R')$ are isomorphic.*

In fact, let $U(z) \in \dot{P}.H.(R)$. Since $\sum_{n=1}^{n_0} \gamma_n$ is compact, there exists a number n' such that $\sum_{n=1}^{n_0} \gamma_n \subset R_{n'}^*$, where R_n^* ($n=1, 2, \dots$) is an exhaustion of R^* with compact relative boundary ∂R_n^* . Put $M = \sup_{z \in R_{n'}^*} U(z)$. Then $M < \infty$. Let $w(\sum_{n=1}^{n_0} \gamma_n, z, R)$ be H.M. of $\sum_{n=1}^{n_0} \gamma_n$. Then $U(z) + Mw(\sum_{n=1}^{n_0} \gamma_n, z, R)$ is superharmonic in R' and $\geq U(z)$, whence $EU(z) \leq U(z) + Mw(\sum_{n=1}^{n_0} \gamma_n, z, R) < \infty$, where E is from R to R' . Let $V(z) \in \dot{P}.H.(R')$. Let $V'(z)$ be L.P.H. in R such that $V'(z) \geq V(z)$ on $\sum_{n=1}^{n_0} \gamma_n$. Then $V'(z) - V(z) > 0$, because if $V(z) = V'(z)$, then $V'(z)$ is harmonic in R' and by the maximum principle $V'(z) = V(z) = 0$. Whence $IV(z) \geq V(z) - V'(z) > 0$, where I is from R' to R . Next we see easily that any $V(z)$ is regular relative to R and $V(z) = 0$ a.e. on $(CR \cap B)$ by $R \cap (R^* - R_n^*) = R' \cap (R^* - R_n^*)$ for $n > n'$, where $R_{n'}^* \supset \sum_{n=1}^{n_0} \gamma_n$.

Theorem 2. *Let R^* be a Riemann surface with positive boundary. Let R be a sub Riemann surface of R^* with relative boundary ∂R in R^* . Let $C_n \supset C'_n \supset C''_n$ ($n=1, 2, \dots$) be discs in R^* such that $\partial C_n + \partial C'_n$ and $\partial C''_n$ may intersect ∂R and $C'_{n,s}$ are disjoint each other. Let γ_n be a continuum in $\partial R \cap C''_n$. Suppose there exists a const. M_n such that*

Fig. 7.

$$(\sup_{z \in \partial C''_n} U(z)) w(\gamma_n, z) \leq M_n U(z) \text{ on } \partial C''_n$$

for any P.H. $U(z)$ in $C_n \cap R^*$ vanishing on $\partial R - \gamma_n$, where $w(\gamma_n, z)$ is H.M. of γ_n with respect to $R'' = R + \sum_{n=1}^{\infty} \gamma_n$.

If $\sum_{n=1}^{\infty} M_n < \infty$, then $\dot{P}.H.(R)$ and $\dot{P}.H.(R'')$ are isomorphic, where R'' is the surface obtained from R by

adding $\sum_{n_0}^{\infty} \gamma_n$ to R , i.e. $R'' - R = \sum_{n_0}^{\infty} \gamma_n$ and $\partial R'' = \partial R - \sum \gamma_n$.

Proof. Let n_0 be a number such that $\prod_{n_0}^{\infty} (1 - 2M_n) \geq \frac{1}{4}$. Let $R' = R + \sum_{n_0-1}^{\infty} \gamma_n$ and $R'' = R + \sum_{n_0}^{\infty} \gamma_n$. Then $R \subset R' \subset R''$. Since $R' - R = \sum_{n_0-1}^{\infty} \gamma_n$ is compact, P.H.(R) and P.H.(R') are isomorphic by Lemma 4. We shall prove P.H.(R') and P.H.(R'') are isomorphic. Let $G''(z, p)$ be the Green's function of R'' . Suppose $p \notin \sum C_n$. Let $M = \max_{z \in \partial C_n''} G''(z, p)$. Consider $G''(z, p) - 2Mw(\gamma_n, z)$ in C_n'' . Since $G''(z, p)$ is a P.H. in $C_n \cap R''$, vanishing on $(\partial R - \gamma_n) \cap C_n$

$$\begin{aligned} G''(z, p) - 2Mw(\gamma_n, z) &\geq \frac{M}{M_n} w(\gamma_n, z) - 2Mw(\gamma_n, z) \\ &= \frac{M}{M_n} (1 - 2M_n) w(\gamma_n, z) > 0 \quad \text{on } \partial C_n''. \end{aligned}$$

Put $\tilde{U}(z) = G''(z, p) - 2Mw(\gamma_n, z)$ for $z \in C_n''$ and $\tilde{U}(z) = \max(G''(z, p) - 2Mw(\gamma_n, z), 0)$ in C_n'' . Since $G''(z, p) \leq M$ and $w(\gamma_n, z) = 1$ on γ_n , the open set $\mathfrak{G} = E[z : G''(z, p) - 2Mw(\gamma_n, z) < 0]$ contains γ_n and does not tend to $\partial C_n''$, whence $\tilde{U}(z)$ is continuous in $R'' - \gamma_n$ except endpoints of γ_n and p , $\tilde{U}(z)$ is subharmonic except p and $\tilde{U}(z) = 0$ on γ_n . Let $G^{r_n}(z, p)$ be the Green's function of $R'' - \gamma_n$. Then $G^{r_n}(z, p)$ is L.P.H. except p where $G^{r_n}(z, p)$ has a logarithmic singularity. Hence

$$G''(z, p) \geq G^{r_n}(z, p) \geq G''(z, p) - 2Mw(\gamma_n, z).$$

Also $G''(z, p) \geq \frac{M}{M_n} w(\gamma_n, z)$ on $\partial C_n''$. By the maximum principle $2Mw(\gamma_n, z) \leq 2M_n G''(z, p)$ for $z \in C_n''$. Hence

$$G''(z, p) \geq G^{r_n}(z, p) \geq G''(z, p) (1 - 2M_n) \quad \text{for } z \in C_n''.$$

Replace $G''(z, p)$ and $G^{r_n}(z, p)$ by $G^{r_n}(z, p)$ and $G^{r_n+r_{n+1}}(z, p)$, where $G^{r_n+r_{n+1}}(z, p)$ is the Green's function of $R'' - \gamma_n - \gamma_{n+1}$. Then as above

$$\begin{aligned} G''(z, p) &\geq G^{r_n}(z, p) \geq G^{r_n+r_{n+1}}(z, p) \geq G^{r_n}(z, p) (1 - 2M_{n+1}) \\ &\geq G''(z, p) (1 - 2M_n) (1 - 2M_{n+1}) \quad \text{for } z \in C_n'' + C_{n+1}''. \end{aligned}$$

In this way we have

$$\begin{aligned} G''(z, p) &\geq G^{\sum_{n_0}^{\infty} \gamma_n}(z, p) \geq G''(z, p) \prod_{n_0}^{\infty} (1 - 2M_n) \geq \frac{G''(z, p)}{4} \\ &\quad \text{for } z \notin \sum_{n_0}^{\infty} C_n'', \end{aligned} \tag{10}$$

where $G_{\sum_{n_0}^{\infty} \gamma_n}(z, p)$ is the Green's function of R' , because $R'' - \sum_{n_0}^{\infty} \gamma_n = R + \sum_1^{n_0-1} \gamma_n = R'$.

In the following we suppose K -Martin's topologies are defined in R'' and R' by using $K''(z, p)$ and $K'(z, p)$, where $K''(z, p) = \frac{G''(z, p)}{G''(z_0, p)}$, $K'(z, p) = \frac{G'(z, p)}{G'(z_0, p)}$ and z_0 is a fixed point in $R - \sum C_n$. Put $\bar{R}' = R' + B'$ and $\bar{R}'' = R'' + B''$, where B' and B'' are ideal boundaries of R' and R'' respectively.

Let $\{p_i\}$ be a sequence determining a point $p' \in B'$ such that $p_i \notin \sum C_n$. Then by (10)

$$\frac{1}{2} K''(z, p_i) \leq K'(z, p_i) \leq 2K''(z, p_i) \quad \text{for } z \notin \sum C_n''. \quad (11)$$

Then we can find a subsequence $\{p'_i\}$ of $\{p_i\}$ such that $\{p'_i\}$ converges to a point $p'' \in B''$. Then

$$\frac{1}{2} K''(z, p'') \leq K'(z, p') \leq 2K''(z, p'') \quad \text{for } z \notin \sum C_n', \quad (12)$$

i.e. there exists at least one point $p'' \in B''$ corresponding to any $p' \in B'$.

Suppose $p_i \in C_m$. Then $K'_{C_m}(z, p_i) = K'(z, p_i)$ for $z \notin C_m$ and $K'_{C_m}(z, p)$ is representable by a positive mass distribution $\mu_{p_i}(q)$ on ∂C_m such that $\int d\mu_{p_i}(q) = 1$ by $K'(z_0, p_i) = 1$ and $K'_{C_m}(z, p_i) = \int_{\partial C_m} K(z, p) d\mu_{p_i}(q)$ for $z \notin C_m$, where $K'_{C_m}(z, p)$ is L.P.H. in R' larger than $K'(z_i, p)$ on C_m . Now since $q \notin C_m$, by (10) $\frac{1}{2} K''(z, q) \leq K'(z, q) \leq 2K''(z, q)$, whence

$$\frac{1}{2} \int K''(z, q) d\mu_{p_i}(q) \leq K'(z, p_i) = \int K'(z, q) d\mu_{p_i}(q) \leq 2 \int K''(z, q) d\mu_{p_i}(q) \quad \text{for } z \notin C_m. \quad (13)$$

Let $\{p_i\}$ be a sequence in R' determining a point $p' \in B'$. Then by (11) and (13) we can find a weak limit $\mu_{p'}(q)$ on B' of $\{\mu_{p_i}(q)\}$ such that

$$\frac{1}{2} \int K(z, q) d\mu_{p'}(q) \leq K'(z, p') \leq 2 \int K''(z, q) d\mu_{p'}(q) \quad \text{for } z \notin \sum C_n''. \quad (14)$$

Let $U(z) \in \dot{P}.H.(R')$ and $U(z_0) = 1$. Then $U(z)$ is representable by a positive mass μ on B' such that $\mu = 0$ on $\partial R' = \partial R'' + \sum \gamma_n$, $\int d\mu = 1$ and

$$U(z) = \int_{B'} K(z, p') d\mu(p').$$

Hence by (14) there exists a function $V(z) \in P^0.H.(R'')$ such that

$$\frac{1}{2} V(z) \leq U(z) \leq 2V(z) \quad \text{for } z \notin \sum C_n'', \quad (15)$$

where

$$V(z) = \left(\int_{B''} K''(z, q) d\mu_{p'}(q) \right) d\mu(p') \quad \text{and} \quad V(z_0) = 1.$$

Similarly for any $V(z) \in \dot{P}.H.(R'')$, $V(z_0)=1$ we can find a $U(z) \in P_0.H.(R')$, $U(z_0)=1$ such that

$$\frac{1}{2} U(z) \leq V(z) \leq 2U(z) \quad \text{for } z \notin \sum C_n. \quad (16)$$

Proof of the theorem. As for non constant positive function $A(z)$, we can suppose without loss of generality $A(z_0)=1$. To define E (from R' to R'') and I (from R'' to R') operations we can use decreasing sequence $\{v_n\}$: $v_n = (R^* - R_n^* - \sum_{m=n_0}^{\infty} C_m)$ instead of $(R^* - R_n^*)$ by the maximum principle, where $\{R_n^*\}$ is an exhaustion of R^* . For example $EU(z) = \lim_n U_n(z)$ for $U(z) \in \dot{P}.H.(R')$, where $U_n(z)$ is L.P.H. in $R' - v_n$ such that $U_n(z) \geq U(z)$ on v_n . $IV(z)$ is defined similarly.

Let $U(z) \in P.H.(R')$. Then by (15) there exists a $V(z) \in \dot{P}.H.(R'')$ such that $U(z) \leq 2V(z)$ on v_n . Hence

$$EU(z) \leq 2V(z) < \infty. \quad (a)$$

Let $V(z) \in \dot{P}_0.H.(R'')$. Then by (16) there exists an $U(z) \in \dot{P}.H.(R')$ such that

$$\frac{U(z)}{2} \leq V(z) \leq U(z) \quad \text{on } v_n,$$

hence

$$0 < \frac{U(z)}{2} \leq IV(z). \quad (b, 1)$$

Also by (15) there exists another $\tilde{V}(z) \in \dot{P}.H.(R'')$ depending on $U(z)$ such that $2\tilde{V}(z) \geq U(z)$. Hence $V(z) \leq 2U(z) \leq 4\tilde{V}(z)$, whence $V(z) \leq 2EU(z) \leq 4\tilde{V}(z) < \infty$

and

$$V(z) \leq 2EU(z). \quad (b, 2)$$

Thus the conditions, a), b, 1) and b, 2) are verified. Hence by the corollary of Theorem 1 $\dot{P}.H.(R')$ and $\dot{P}.H.(R'')$ are isomorphic and $\dot{P}.H.(R)$ and $\dot{P}.H.(R'')$ are isomorphic.

Corollary. Under the condition of Theorem 2 any positive minimal harmonic function in R'' vanishing on $\partial R''$ is the image of a uniquely determined minimal function in R vanishing on ∂R by the operation E and

conversely any minimal function in R vanishing on ∂R is the image of a uniquely determined minimal function in R'' vanishing on $\partial R''$ and the correspondence is one-to-one manner.

Example 1. Let R^* be a unit circle, $R^*: |z| < 1$ and let I be a straight on the real axis, $I: \operatorname{Im} z = 0, 0 \leq \operatorname{Re} z \leq 1$. Put $R = R^* - I$. Let C_n ($n = 1, 2, \dots$) be a hyperbolic circle with centre at $q_n: 1 - \frac{1}{4^n}$ and with hyperbolic radius

$$\frac{1}{3}, \text{ i.e. } C_n: \left| \frac{z - 1 + \frac{1}{4^n}}{1 - \left(1 - \frac{1}{4^n}\right)z} \right| < \frac{1}{3}. \text{ Then } C_n \text{ intersects } I \text{ at } 1 -$$

$$\frac{\frac{4}{3}}{4^n \left(\frac{2}{3} + \frac{1}{3 \times 4^n} \right)} \text{ and } 1 - \frac{\frac{2}{3}}{4^n \left(\frac{4}{3} - \frac{1}{3 \times 4^n} \right)} \text{ and } \{C_{n,s}\} \text{ are disjoint each other.}$$

Let s_n be a straight on I of hyperbolic length $2\delta_n < \frac{1}{12}$ with its middle point

$$\text{at } q_n, s_n: \operatorname{Im} z = 0, 1 - \frac{1 + \delta_n}{4^n \left(1 - \delta_n + \frac{\delta_n}{4^n} \right)} \leq \operatorname{Re} z \leq 1 - \frac{1 - \delta_n}{4^n \left(1 + \delta_n - \frac{\delta_n}{4^n} \right)}. \text{ Let } R'' =$$

$R + \sum_{n=1}^{\infty} s_n$. Suppose K -Martin's topology is defined in R'' and

$$\sum_{n=1}^{\infty} \delta_n < \infty.$$

Fig. 8.

Then R'' has the following properties.

1). There exist only two minimal points p^U and p^L on $z = 1$.

2). Let $\{p_i^U\}$ ($i = 1, 2, \dots$) ($\{p_i^L\}$) be a sequence in $R'' - \sum_{n=1}^{\infty} C_n$ tending to $z = 0$ such that the imaginary part of p_i^U , $\operatorname{Im} p_i^U > 0$ ($\operatorname{Im} p_i^L < 0$). Then $K''(z, p_i^U) \rightarrow K''(z, p^U)$ and $K''(z, p_i^L) \rightarrow K''(z, p^L)$ as $i \rightarrow \infty$, where $K''(z, p^U)$ and $K''(z, p^L)$ are minimal

functions corresponding to p^U and p^L and $K''(z, p_i)$ are normalized as $K''\left(-\frac{1}{2}, p_i\right) = 1$.

3). Let $p_i \in \sum_{n=1}^{\infty} s_n$. Then $K(z, p_i) \rightarrow \frac{1}{2}(K''(z, p^U) + K''(z, p^L))$, i.e. any sequence $\{p_i\}$ on $\sum_{n=1}^{\infty} s_n$ determines a non minimal point. Let D_n ($n = 1, 2, \dots$) be a domain $\ni q_n$ and $\{(D_n - q_n)\}$ are all conformally equivalent. Let $\{p_i\}$

be a fundamental sequence in $\sum_n^\infty D_n$. Then $\{p_i\}$ determines a non minimal boundary point on $z=1$.

Map C_n conformally onto $|w| < \frac{1}{3}$. Then by Lemma 3), there exists a const. M such that for any positive harmonic function $U(w)$ in $|w| < \frac{1}{3}$ vanishing on the image of $I-s_n$ and $M\delta_n U(w) \geq \sup_{|w|=\frac{1}{12}} U(w)w(s'_n, w)$, where $w(s'_n, w)$ is H.M. of the image of s_n relative to $|w| < 1$. Put $M_n = M\delta_n$, then $\sum M_n < \infty$. Let $\dot{P}.H.(R'')$ and $\dot{P}.H.(R)$ be the sets of P.H. functions in R'' and R vanishing on $1 - \sum_{n=1}^\infty s_n$ and I respectively. Then by Theorem 2 $\dot{P}.H.(R'')$ and $\dot{P}.H.(R)$ are isomorphic. It is more convenient to consider the relation between $\dot{P}.H.(R'')$ and $\dot{P}.H.(R')$, where $R' = R + \sum_{n=1}^{n_0} s_n$ and n_0 is a number such that

$$\prod_{n_0}^\infty (1 - 2M_n) \geq \frac{1}{4}. \quad (17)$$

Suppose K -Martin's topologies are defined in R'' and R' by $K''(z, p)$ and $K'(z, p)$ respectively, where they are normalized as $K''\left(-\frac{1}{2}, p\right) = K'\left(-\frac{1}{2}, p\right) = 1$. Let v be a sufficiently small euclidean neighbourhood of $z=1$. Then since $v \cap R'$ consists of two simply connected domains, there exist only two points p^v and p^L on $z=1$ which are minimal and the corresponding functions, $K'(z, p^v)$ and $K'(z, p^L)$ have the properties. 1). $K'(z, p^v) = K'(\bar{z}, p^L)$, where $\bar{z}$ is the conjugate of z . 2). $K'(z, p^v) \rightarrow \infty$ as $z \rightarrow 1$ in the upper half plane and $K'(z, p^v) < L < \infty$ in the lower half plane. Let $v_n = E\left[z: |z| > 1 - \frac{1}{n}\right]$. Then E and I operations between R' and R'' are defined with respect to $\{v_n\}$. Then by the condition (17)

$$\begin{aligned} EU(z) < \infty \quad \text{and} \quad IEU(z) = U(z) & \quad \text{for} \quad U(z) \in \dot{P}.H.(R'), \\ IV(z) > 0 \quad \text{and} \quad EIV(z) = V(z) & \quad \text{for} \quad V(z) \in \dot{P}.H.(R''), \end{aligned} \quad (18)$$

$$\frac{1}{2} K'(z, p) \leq K''(z, p) \leq 2K'(z, p) \quad \text{for} \quad z \notin \sum_{n_0}^\infty C_n. \quad (19)$$

We see at once 1). $EK'(z, p^v) = EK'(\bar{z}, p^L)$ and by (19) $EK'(z, p^v) \rightarrow \infty$ as $z \rightarrow 1$ outside of $\sum C_n$ in the upper half plane and $EK'(z, p) < 2L$ for $z \in \sum C_n$ and $\text{Im } z < 0$. 2). $EK'(z, p^v)$ and $EK'(z, p^L)$ are minimal by the minimality of $K'(z, p^v)$ and $K'(z, p^L)$. Let $\{p_i\}$ be a sequence in R'' determining an ideal

boundary point on $z=1$, i.e. $K''(z, p_i)$ converges to a $K(z, p)$ as $p_i \rightarrow z=1$. Then clearly $K''(z, p)=0$ on $I - \sum_{n_0}^{\infty} s_n$ and $|z|=1$ except $z=1$. By (18) and since there exist only two points of the boundary points of R' on $z=1$, $IK''(z, p)$ has the form

$$\begin{aligned} IK''(z, p) &= \alpha K'(z, p^v) + \beta K'(z, p^L) \quad \text{and} \\ K''(z, p) &= EIK''(z, p) = E(\alpha K'(z, p^v) + \beta K'(z, p^L)). \end{aligned} \quad (20)$$

Hence there exist only two minimal boundary points of R'' on $z=1$.

Let $\{p_i\}$ be any sequence in $R'' - \sum_{n_0}^{\infty} C_n$ such that $p_i \rightarrow z=1$ and p_i lies in the upper half plane. Let $\{p'_i\}$ be a subsequence of $\{p_i\}$ such that $K''(z, p'_i) \rightarrow K''(z, p)$. Then by (19) $K''(z, p) < 2L$ in the lower half plane outside of $\sum_{n_0}^{\infty} C_n$. Whence the representation (20) of $K''(z, p)$ has the form $K''(z, p) = \alpha EK'(z, p^v)$, where α is given by $K''\left(-\frac{1}{2}, p\right) = \alpha EK'\left(-\frac{1}{2}, p^v\right)$ and does not depend on the subsequence $\{p'_i\}$. Hence $\{p_i\}$ converges to p on $z=1$ of R'' (p corresponds to $K''(z, p^v)$). Similarly for any sequence $\{p_i\}$ in $R'' - \sum_{n_0}^{\infty} C_n$ in the lower half plane, $K''(z, p_i) \rightarrow K''(z, p^L)$. Thus we have the property (1).

Let $\{p_i\}$ be a sequence on $\sum_{n_0}^{\infty} s_n$. Then by $K''(z, p_i) = K''(\bar{z}, p_i)$, $K''(z, p_i) \rightarrow \frac{1}{2}(K''(z, p^v) + K''(z, p^L))$ as $i \rightarrow \infty$. Let $\{p'_i\}$ be a sequence of $\{p_i\}$ in $\sum_{n_0}^{\infty} D_n$ such that $p_i \rightarrow z=1$ and $K''(z, p_i)$ converges to $K''(z, p)$ as $i \rightarrow \infty$. Let q_n be the middle point of s_n . Then as above $K''(z, q_i) \rightarrow \frac{1}{2}(K''(z, p^v) + K''(z, p^L))$ as $i \rightarrow \infty$. Since $G''(z, p)$ of R'' is a harmonic function of p for fixed $z \notin \sum_{n=n_0}^{\infty} D_n$, there exists by Harnack's theorem a const. M depending on D_n but non on n by the conformal equivalency of D_n such that

$$\frac{1}{M} \leq \frac{G''(z, p_i)}{G''(z, q_i)} \leq M \quad \text{and} \quad \frac{1}{M} \leq \frac{G''\left(-\frac{1}{2}, p_i\right)}{G''\left(-\frac{1}{2}, q_i\right)} \leq M.$$

Hence $\frac{1}{M^2} \leq \frac{K''(z, p_i)}{K''(z, q_i)} \leq M^2$ for $z \notin \sum_{n=n_0}^{\infty} C_n$.

Let $i \rightarrow \infty$. Then $K''(z, p_i) \rightarrow K''(z, p)$ and

$$\frac{1}{M^2} \leq \frac{\frac{1}{2}(K''(z, p^v) + K''(z, p^L))}{K''(z, p)} \leq M^2, \quad z \notin \sum_{n=0}^{\infty} C_n. \quad (21)$$

Consider $K''(z, p)$ and $\frac{1}{2}(K''(z, p^v) + K''(z, p^L))$ in the upper half plane outside of $\sum_{n=0}^{\infty} C_n$. Then since $K''(z, p) \leq 2L$, $\frac{M^2}{2} \geq \alpha \geq \frac{1}{2M^2} > 0$ in the form, $K''(z, p) = \alpha K''(z, p^v) + \beta K''(z, p^L)$. Similarly we have $\beta \geq \frac{1}{2M^2}$. Hence $K''(z, p)$ is non minimal and $\{p_i\}$ determines a non minimal point of R'' . Thus we have the property (2).

Remark. In Example 1, we can take a circle $\tilde{C}_n$ of hyperbolic radius r_n with centre at q_n (r_n and q_n depend on n) instead of C_n . Let $I_n = E[z: 1 + r_n e^{i\theta_n}]$ ($n=1, 2, \dots$), $0 < r_n < -2l_n \cos \theta_n$, $\pi > \theta_n > \frac{\pi}{2}$. Let $s_{n,m}$ ($m=1, 2, \dots$) be a straight on I_n . Then we can choose $s_{n,m}$ so small that there exist infinitely many K -Martin's minimal boundary points of R''' on $z=1$, where $R''' = \text{unit circle} - \sum_n I_n + \sum_{n,m} s_{n,m}$.

In Example 1 we discussed $\dot{P}.H.(R'')$ by $\dot{P}.H.(R)$, when R increased to R'' . We show an example to consider $\dot{P}.H.(R'')$ by $P.H.(R)$, when R decreases to R'' .

Example 2. Let $R: |z| < 1$ and let C_n be a hyperbolic circle with hyperbolic radius $\frac{1}{3}$ and its centre at q_n also let S_n be a concentric hyperbolic circle with hyperbolic radius δ_n . Suppose C_n 's are disjoint each other and

$$\sum_{n=1}^{\infty} \frac{1}{-\log \delta_n} < \infty.$$

Put $R'' = R - \sum_{n=1}^{\infty} S_n$. Let $\dot{P}.H.(R)$ be the class of $P.H.$ functions in $|z| < 1$ and let $\dot{P}.H.(R'')$ be of $P.H.$ functions vanishing on $\sum_{n=1}^{\infty} S_n$. Then $\dot{P}.H.(R)$ and $\dot{P}.H.(R'')$ are isomorphic. Especially there exist only one K -Martin's boundary point of R'' which is minimal at $e^{i\theta}$.

In fact, map C_n onto $|\zeta| < \frac{1}{3}$ and let $U(\zeta)$ be a $P.H.$ in $|\zeta| < \frac{1}{6}$. Then there exists a const. M such that $\max_{|\zeta|=\frac{1}{12}} U(\zeta) \leq M \min_{|\zeta|=\frac{1}{6}} U(\zeta)$. Let C'_n and C''_n be concentric circles as C_n with hyperbolic radius $\frac{1}{6}$ and $\frac{1}{12}$ respectively. Then $w(S_n, z) = \frac{\log 12}{-\log \delta_n}$ on $\partial C''_n$, where $w(S_n, z)$ is H.M. of S_n relative to $|z| < 1$.

Put $M_n = M \frac{\log 12}{-\log \delta_n}$. Then $M_n \min_{z \in \partial C'_n} U(z) \geq \max_{z \in \partial C'_n} U(z) w(S_n, z)$. Hence by Theorem 1, $\dot{P}.H.(R)$ and $\dot{P}.H.(R'')$ are isomorphic and there exists only one boundary point R at $e^{i\theta}$ which is minimal.

Let R be a Riemann surface with positive boundary and let R_0 be a compact disc. Let $N(z, p)$ be an N -Green's function in $R - R_0$ such that $N(z, p) = 0$ on ∂R_0 , $N(z, p)$ has a logarithmic singularity at p and $N(z, p)$ has minimal Dirichlet integral (Dirichlet integral is taken about $N(z, p) + \log |z - p|$ in a neighbourhood of p). Suppose the N -Martin's⁹⁾ topology is defined on $R - R_0$. We shall construct a Riemann surface of planer character in which there exist non N -minimal points.

Example 3. Let C be a unit circle, $C: |z| < 1$. Let s_n ($n=1, 2, \dots$) be a straight, $s_n: \operatorname{Im} z = 0, 0 < a_n \leq \operatorname{Re} z \leq b_n, a_n < b_n \dots < a_1 < b_1 = 1$ in C and let $t_n: \operatorname{Im} z = 0, b_{n+1} \leq \operatorname{Re} z \leq a_n$. Let $\hat{s}_n$ and $\hat{t}_n$ be symmetric images of s_n and t_n with respect to the imaginary axis. Let I be a straight such that $I: \operatorname{Re} z = 0, 0 < \operatorname{Im} z < \frac{1}{2}$ and $0 > \operatorname{Im} z > -\frac{1}{2}$.

Condition. $z=0$ is contained in the closure of $\sum s_n$ and $\sum s_n$ is so thinly distributed as $z=0$ is an irregular point for the Dirichlet problem in $C - \sum (s_n + \hat{s}_n)$. Put $R - R_0 = C - I - \sum (t_n + \hat{t}_n)$. Then there exist four N -minimal points and non N -minimal points of $R - R_0$ on $z=0$.

Let $p_i = r_i e^{i\theta_i}$. Suppose $r_i \rightarrow 0$ as $i \rightarrow \infty$ and $\frac{\pi}{2} > \theta_i > \delta > 0$. Then p_i determines an N -minimal point⁹⁾. Similar fact occurs in each sector $S_j: 0 < |z| < 1, \frac{\pi(j-1)}{2} \leq \arg z \leq \frac{\pi j}{2}, (j=1, 2, 3, 4)$.

Fig. 9.

Let $N(z, p)$ be an N -Green's function of $R - R_0$. Then $N(z, p) = 0$ on ∂R_0 , $\frac{\partial}{\partial n} N(z, p) = 0$ on $\sum (t_n + \hat{t}_n) + I$.

Let $G(z, p)$ be the Green's function of C . Then

$$N(z, p_i) + N(z, \bar{p}_i) + N(z, \hat{p}_i) + N(z, \hat{\bar{p}}_i) = G(z, p_i) + G(z, \bar{p}_i) + G(z, \hat{p}_i) + G(z, \hat{\bar{p}}_i),$$

where $\bar{p}$ and $\hat{p}$ are the conjugate of p and the symmetric image of p with respect to I .

Let $p_i \rightarrow p$ on $z=0$. Then

9) See (8).

$$N(z, p) + N(z, \bar{p}) + N(z, \hat{p}) + N(z, \hat{\bar{p}}) = -4 \log |z|.$$

Let C' be a circle, $C': |z| < \frac{2}{3}$ and put $\Omega_s = C' - \sum (s_n + \hat{s}_n)$. Let $G'(z, p)$ be the Green's function of Ω_s . By the condition, $z=0$ is an irregular point for also the Dirichlet problem in Ω_s . Hence there exists a sequence $\{p_i\}$ such that $\lim_i G'(z, p_i) = G'(z, p) > 0$. Let $v_n = \left[z: |z| < \frac{1}{n} \right]$. We define E and I operations between C and Ω_s with respect to $\{v_n\}$. Then by $G(z, p_i) \geq G'(z, p_i)$, $EG'(z, p) < \infty$. Now $EG'(z, p)$ is harmonic in C except $z=0$, whence $EG'(z, p)$ must be $\alpha(-\log |z|)$ (α is a positive constant ≤ 1). By $IEG'(z, p) = G'(z, p)$, $I(-\log |z|)$ is a harmonic function in Ω_s such that $I(-\log |z|) \leq (-\log |z|)$, $I(-\log |z|) = 0$ on $\sum (s_n + \hat{s}_n)$, $\frac{\partial}{\partial n} I(-\log |z|) = 0$ on $I + \sum (t_n + \hat{t}_n)$. Hence for any p on $z=0$: $p = \lim_i p_i$,

$$-4 \log |z| = N(z, p) + N(z, \bar{p}) + N(z, \hat{p}) + N(z, \hat{\bar{p}}) \geq 4I(-\log |z|) > 0. \quad (22)$$

Let R' be the part of $R - R_0$ over $|z| < \frac{2}{3}$. Put $R_s = R' - \sum (s_n + \hat{s}_n)$. Then R_s consists of four components, R'_j ($j=1, 2, 3, 4$), where $R'_j \subset S_j$. Suppose $p_i \in R'_j$. Let $N^s(z, p_i)$ be an N -Green's function in R_s such that $N^s(z, p_i)$ is harmonic in R_s , $N^s(z, p_i)$ has a logarithmic singularity at p_i , $N^s(z, p_i) = 0$ on $\sum (s_n + \hat{s}_n)$ and on $|z| = \frac{2}{3}$, $\frac{\partial}{\partial n} N^s(z, p_i) = 0$ on $\sum (t_n + \hat{t}_n) + I$ and $N^s(z, p_i) = 0$ in R'_j for $j' \neq j$. Then

$$\begin{aligned} -4 \log |z| &\geq \lim_i (N^s(z, p_i) + N^s(z, \bar{p}_i) + N^s(z, \hat{p}_i) + N^s(z, \hat{\bar{p}}_i)) \\ &= \lim_i (G'(z, p_i) + G(z, \bar{p}_i) + G(z, \hat{p}_i) + G(z, \hat{\bar{p}}_i)) \\ &= 4\alpha I(-\log |z|), \end{aligned} \quad (23)$$

α depends on $\{p^i\}$ and $1 \geq \alpha \geq 0$.

We shall use $I^{N, \Gamma}$ and $E^{N, \Gamma}$ operations between $R - R_0$ and R_s , where $\Gamma = I + \sum (t + \hat{t}_n)$. Since $I(-\log |z|) = 0$ on $\sum (s_n + \hat{s}_n)$, $\frac{\partial}{\partial n} I(-\log |z|) = 0$ on $I + \sum (t_n + \hat{t}_n)$, $I^{N, \Gamma}$ can be defined and we have by (22)

$$I^{N, \Gamma}(\lim_i N(z, p_i)) > 0 \quad \text{for any } p_i \rightarrow p \text{ on } z=0. \quad (24)$$

Suppose $\lim_i N^s(z, p_i)$ exists and > 0 . Then by (23)

$$E^{N, \Gamma}(\lim_i N^s(z, p_i)) > 0. \quad (25)$$

We can find a sequence $\{p_i\}$ such that $\lim_i G'(z, p_i) = \beta I(-\log |z|) > 0$. Then by (23) $E^{N,r}(\lim_i (N^s(z, p_i) + N^s(z, \bar{p}_i) + N^s(z, \hat{p}_i) + N^s(z, \hat{\bar{p}}_i))) = 4\beta EI(-\log |z|)$. On the other hand, since $\frac{\partial}{\partial n} I(-\log |z|) = 0$ on $I + \sum (t_n + \hat{t}_n)$, $E^{N,r}(I(-\log |z|)) = EI(-\log |z|) = -\log |z|$. Put $U(z) = \frac{4}{\beta} \lim_i (N^s(z, p_i) + N^s(z, \bar{p}_i) + N^s(z, \hat{p}_i) + N^s(z, \hat{\bar{p}}_i)) > 0$. Then $U(z) = 0$ on $\sum (s_n + \hat{s}_n)$ and on $|z| = \frac{2}{3}$, $\frac{\partial}{\partial n} U(z) = 0$ on $I + \sum (t_n + \hat{t}_n)$, $E^{N,r} U(z) = -4 \log |z|$ and for any $p_j \rightarrow p$ on $z=0$

$$E^{N,r} U(z) = -4 \log |z| = N(z, p) + N(z, \bar{p}) + N(z, \hat{p}) + N(z, \hat{\bar{p}}).$$

Hence by Theorem 1, N, a) and e) and (24)

$$E^{N,r} I^{N,r} N(z, p) = N(z, p) > 0 \quad \text{for any } p \text{ on } z=0. \quad (26)$$

Let $\mathring{\text{P.H.N.}}(R)$ be the set of positive harmonic function $U(z)$ of the form $N(z, p)$ in $R - R_0$ except $z=0$ such that $U(z)=0$ on ∂R_0 , $\frac{\partial}{\partial n} U(z)=0$ on $\sum (t_n + \hat{t}_n) + I$ and let $\mathring{\text{P.H.N.}}(R_s)$ be the set of positive harmonic function $V(z)$ of the form $N^s(z, p)$ in R_s except $z=0$ such that $V(z)=0$ on $|z| = \frac{2}{3}$ and $\sum (s_n + \hat{s}_n)$ and $\frac{\partial}{\partial n} V(z)=0$ on $I + \sum (t_n + \hat{t}_n)$. Then $\mathring{\text{P.H.N.}}(R)$ and $\mathring{\text{P.H.N.}}(R_s)$ are isomorphic by (25) and (26).

Let $N^s(z, p) = \lim_i N^s(z, p_i) > 0$: $p_i \in R_j''$ and $p_i \rightarrow p$ on $z=0$. We shall show that $N^s(z, p)$ is N -minimal in R_s . Let $U(z)$ be a superharmonic function in R_s such that $N^s(z, p) - U(z) > 0$ is also superharmonic in R_s . Now $\frac{\partial}{\partial n} N^s(z, p) = 0$ on $I + \sum (t_n + \hat{t}_n)$. This means $N^s(z, p)$ has no mass on $I + \sum (t_n + \hat{t}_n)$, whence by the superharmonicity of $N^s(z, p) - U(z)$, $\frac{\partial}{\partial n} U(z) = 0$ on $I + \sum (t_n + \hat{t}_n)$. Put $\mathring{V}(z) = N^s(z, p) = N^s(z, \hat{p}) = N^s(z, \bar{p}) = N^s(z, \hat{\bar{p}})$ in each R_j'' . Also define $\mathring{U}(z)$ similarly from $U(z)$ into $R - R_0$. Then $\mathring{U}(z)$ and $\mathring{V}(z)$ is harmonic in $C' - \sum (s_n + \hat{s}_n)$, where $C': |z| < \frac{2}{3}$. Now there exists only one linearly independent harmonic function $I(-\log |z|)$ in this surface. Whence $\mathring{U}(z) = \alpha \mathring{V}(z) = \beta I(-\log |z|)$ and $U(z) = \alpha N^s(z, p)$ and $N^s(z, p)$ is N -minimal in R_s . On the other hand, in every R_j'' , $N^s(z, p)$ exists denoted by $N^s(z, p^j)$. Then clearly $N^s(z, p^j)$ are linearly independent. Because $N^s(z, p_j) = 0$ in R_j'' , for $j' \neq j$. Let $N(z, p) = \lim_i N(z, p_i)$. Then by (26) $I^{N,r} N(z, p) > 0$, whence $I^{N,r}(z,$

$p) = \sum_{j=1}^4 \alpha_j N^s(z, p^j)$. Next also by (26) $N(z, p) = \sum_j \alpha_j E^{N, \Gamma} N^s(z, p^j)$ and there exist exact four N -minimal points of $R - R_0$ on $z=0$.

Property of $E^{N, \Gamma} N^s(z, p^j)$. $N^s(z, p^j) = 0$ in R''_j for $j' \neq j$. Hence

$$E^{N, \Gamma} N^s(z, p^j) = E_{R''_j}^{N, \Gamma} N^s(z, p^j),$$

where $E_{R''_j}^{N, \Gamma}$ is from R''_j to $R - R_0$ and $E^{N, \Gamma}$ is from R_s to $R - R_0$.

By Theorem N.1). b)

$$\begin{aligned} I_{R''_k}^{N, \Gamma} E_{R''_j}^{N, \Gamma} N^s(z, p^j) &\leq E_{R''_k}^{N, \Gamma} E_{R''_j}^{N, \Gamma} N^s(z, p^j) \leq E_{CR''_j}^{N, \Gamma} E_{R''_j}^{N, \Gamma} N^s(z, p^j) = 0 \quad \text{and} \\ I_{R''_j}^{N, \Gamma} E_{R''_j}^{N, \Gamma} N^s(z, p^j) &= N^s(z, p^j) \quad \text{for } k \neq j. \end{aligned} \quad (27)$$

We shall show $p_i = r_i e^{i\theta_j} \left(\frac{\pi}{2} \geq \theta_j > \delta > 0 \right) \in S_i$ determines an N -minimal point p^i of $R - R_0$. $N(z, p_i) + N(z, \hat{p}_i) = N(z, \bar{p}_i) + N(z, \hat{\bar{p}}_i) = U(z, p_i)$ for $\text{Im } z = 0$, where $U(z, p_i) = \frac{1}{2} (G(z, p_i) + G(z, \bar{p}_i) + G(z, \hat{p}_i) + G(z, \hat{\bar{p}}_i))$ and $G(z, q) = \log \frac{|1 - \bar{q}z|}{|z - q|}$.

$N(z, p_i)$ is harmonic in S_i (has no singularity) such that $\frac{\partial}{\partial n} N(z, p_i) = 0$ on $I + \sum_{n=1}^{\infty} (t_n + \hat{t}_n)$ and $N(z, p_i) \leq U(z, p_i)$ on $\sum_{n=1}^{\infty} (s_n + \hat{s}_n) + I' \left(= E \left[z : \text{Re } z = 0, -1 \leq \text{Im } z \leq -\frac{1}{2} \right] \right)$ and $N(z, p_i) = \frac{1}{2\pi} \int_{\Sigma s_n + I'} N(\zeta, p_i) \frac{\partial}{\partial n} N^s(\zeta, z) ds$ in S_i , where $N^s(\zeta, z)$ is a harmonic function in S_i such that $N^s(\zeta, z)$ has a logarithmic singularity at z , $\frac{\partial}{\partial n} N^s(\zeta, z) = 0$ on $I + \sum_{n=1}^{\infty} t_n$ and $N^s(\zeta, z) = 0$ on $|z| = 1$ and on $\sum_{n=1}^{\infty} s_n + I'$.

Put $p_i = r_i e^{i\theta_i}$. Then by $\frac{\pi}{2} > \theta_i > \delta$, $\frac{5}{4} > |1 - p_i \zeta| > \frac{3}{4}$ for $r_i < \frac{1}{4}$ and $|\zeta - p_i| \geq \zeta \sin \zeta$. Hence there exists a const. A such that

$$U(\zeta, p_i) \leq -2 \log |\zeta| + A \quad \text{for } |r| \leq \frac{1}{4},$$

whence $N(\zeta, p_i) \frac{\partial}{\partial n} N^s(\zeta, z)$ is uniformly integrable on $\sum_{n=1}^{\infty} s_n + I'$ for $|p_i| \leq \frac{1}{4}$.

Hence $N(z, p^i) = \frac{1}{2\pi} \int_{\Sigma s_n + I'} N(\zeta, p^i) \frac{\partial}{\partial n} N^s(\zeta, z) ds = U(z)$ in S_i ,

where $N(z, p^i) = \lim_i N(z, p_i)$.

$I_{R''_i}^{N, \Gamma} N(z, p^i) = \lim_n V_n(z)$, where $V_n(z)$ is a harmonic function in $R''_i \cap E \left[|z| > \frac{1}{n} \right]$ such that $V_n(z) = U(z)$ on $|z| = \frac{1}{n}$, $\frac{\partial}{\partial n} V_n(z) = 0$ on $I + \sum_{n=1}^{\infty} t_n$, $V_n(z) = 0$ on

$I' + \sum s_n$ and on $|z| = \frac{2}{3}$. Let $w_n(z)$ be a harmonic function in $R'_4 \cap E\left[|z| > \frac{1}{n}\right]$ such that $w_n(z) = 0$ on $|z| = \frac{1}{n}$ and $\frac{\partial}{\partial n} w_n(z) = 0$ on I and $w_n(z) = U(z)$ on $\sum s_n + I'$ and on $|z| = \frac{2}{3}$. Then $w_n(z) = \frac{1}{2\pi} \int_{\Sigma s_n + I'} N(\zeta, p) \frac{\partial}{\partial n} N_n^s(\zeta, z) ds$, $U(z) = w_n(z) + V_n(z)$ and $\lim_n w_n(z) = U(z)$ by $\frac{\partial}{\partial n} N_n^s(\zeta, z) \uparrow \frac{\partial}{\partial n} N^s(\zeta, z)$, where $N_n^s(\zeta, z)$ is a function in $R'_4 \cap E\left[|z| > \frac{1}{n}\right]$ such that $N_n^s(\zeta, z)$ has singularity at z , $N_n^s(\zeta, z) = 0$ on $I' + \sum s_n$ and $|z| = \frac{1}{n}$ and $\frac{\partial}{\partial n} N_n^s(\zeta, z) = 0$ on $I + \sum t_n$. Whence $\lim_n V_n(z) = I_{R'_4}^{N, \Gamma} N(z, p) = 0$. Similarly we have

$$I_{R'_k}^{N, \Gamma} N(z, p^1) = 0 \quad \text{for } k \neq 1. \quad (28)$$

Hence in the form $N(z, p) = \sum_j^4 \alpha_j E^{N, \Gamma} N^s(z, p^j) \cdot \alpha_k = 0: k \neq 1$ and $N(z, p^1) = \alpha_1 E^{N, \Gamma} N^s(z, p^1)$. Now by $\int_{|z|=1} \frac{\partial}{\partial n} N(z, p) ds = 2\pi$, α_1 does not depend on special sequence $\{p_i\}$ if $\frac{\pi}{2} \geq \arg p_i > \delta > 0$. Hence any $\{p_i\}$ determines an N -minimal point on $z=0$ as $p_i \rightarrow z=0$, if $\frac{\pi}{2} > \arg p_i > \delta > 0$. Similar fact occurs in S_k , $k=2, 3, 4$.

Let $p_i \in \sum s_n$. Then we have at once $\lim_i N(z, p_i) = \frac{1}{2} (N(z, p^1) + N(z, p^4))$ and $\{p_i\}$ determines a non N -minimal point on $z=0$.

Remark. It is easy to construct a boundary point $z=0$ on which infinitely many N -minimal points exist as the remark of Example 1.
