Running head: *Acidocella aquatica* sp. nov.

Subject category: New taxa: *Proteobacteria*

The GenBank/EMBL/DDBJ accession numbers for the 16S rRNA gene sequences of strain Ok2G^T is LC199502.

27 **Summary**

28 A novel acidophilic heterotrophic bacterium, strain Ok2G^T, was isolated from a freshwater lake in Japan.
29 Cells of the isolate were Gram-stain-negative and non-motile rods (0.6–0.8×1.0–2.8 μm). Growth was
30 observed at 4–35°C with an optimum growth temperature of 28°C. The range of pH for growth was 3.0–6.2
31 with an optimum pH of 4.5. The strain utilized fructose, glucose, sucrose, mannitol, sorbitol, ethanol, benzyl
32 alcohol, pyruvate, yeast extract and tryptone as carbon and energy sources for aerobic growth. DNA G+C
33 content was 62.6 mol%. The major cellular fatty acid and isoprenoid quinone were summed feature 8 (C_{18:1}
34 ω7c and/or C_{18:1}ω6c) and Q-10, respectively. Phylogenetic analysis based on the 16S rRNA gene sequence
35 indicated that strain Ok2G^T belongs to the genus *Acidocella* but is distinct from existing species with sequence
36 similarities lower than 97%. On the basis of these results, strain Ok2G^T (=NBRC 112502^T =DSM 104037^T) is
37 proposed as the type strain of a novel species, *Acidocella aquatica* sp. nov.

38

39

40 The genus *Acidocella* within the class *Alphaproteobacteria* was proposed in 1995, along with an emendation
41 of the genus *Acidiphilium* [1]. It originally contained two species transferred from the genus *Acidiphilium* (*A.*
42 *facilis* and *A. aminolytica*), and *A. aluminidurans* was added to the genus later [2]. In addition to these three
43 species with validly published name, “*A. aromatica*” was also proposed in this genus [3]. All type strains of
44 these species are acidophilic and mesophilic heterotrophs isolated from acidic environments [2, 3, 4, 5]. Some
45 other members of this genus have also been isolated from environments affected by acidic mine drainage [6, 7,
46 8]. In this study, a novel bacterium related to these organisms was isolated, and its physiological, biochemical
47 and phylogenetic characteristics are reported.

48
49 Strain Ok2G^T was isolated from a freshwater lake (Lake Okotanpe) in Hokkaido, northeastern Japan. A
50 sample of lake water was taken at 10 m depth from the lake surface. Temperature and pH of the sample was
51 11.3°C and 5.9 respectively. An aliquot of the sample (0.5 ml) was inoculated into 10 ml of a synthetic liquid
52 medium consisting of the following constituents (l⁻¹): 0.5 g glucose, 0.3 g MgSO₄·7H₂O, 0.1 g CaCl₂·2H₂O,
53 0.1 g KCl, 0.2 g NaNO₃, 0.1 g methylphosphonic acid and 1 ml trace element solution SL-10 [9]. The culture
54 was incubated under aerobic conditions in the dark at 15°C. A pure culture of strain Ok2G^T was obtained by
55 repeated serial dilution in the same medium. The culture purity was checked by microscopy, observation of
56 colony morphology and repeated sequencing of the 16S rRNA gene fragments amplified with universal PCR
57 primer pairs.

58 For physiological and biochemical characterization of strain Ok2G^T, another synthetic medium was prepared.
59 The medium was modified from that used for isolation, to contain NH₄Cl (0.1 g l⁻¹) and KH₂PO₄ (0.1 g l⁻¹),
60 instead of NaNO₃ and methylphosphonic acid. The concentration of glucose was increased to 1 g l⁻¹ and pH
61 was adjusted to 3–5 with hydrochloric acid. This basal medium was used for the characterization unless
62 otherwise specified.

63 Cell morphology was examined by phase-contrast microscopy (Axioplan 2; Zeiss). Colony morphology was
64 observed on 1.5% (w/v) agar-solidified basal medium with increased glucose concentration of 10 g l⁻¹. The

65 Gram-staining test was carried out using a kit (Fluka). Catalase activity was assessed by pouring 3% H₂O₂
66 solution onto a pellet of cells. Oxidase activity was carried out using an oxidase test reagent (bioMérieux).
67 The genomic G+C content of the DNA was determined with HPLC methods [10], using a kit (Yamasa Shoyu).
68 Isoprenoid quinone was analyzed at Techno Suruga (Shizuoka, Japan) by using the ACQUITY UPLC system
69 (Waters).

70 The cellular fatty acid profile of strain Ok2G^T was analyzed in parallel with those of the type strains
71 representing *Acidocella* species as references for comparisons. The following strains were purchased from
72 DSM, ATCC and NBRC; “*A. aromatica*” DSM 27026 (=PFBC), *A. aminolytica* DSM 11237 (=101^T), *A.*
73 *aluminiumdurans* NBRC 104303 (=AL46^T) and *A. facilis* ATCC 35904 (=PW2^T). All strains were cultured under
74 identical conditions using the basal medium containing fructose (1 g l⁻¹), instead of glucose. The strains were
75 cultured at 28°C for 5 days without shaking, and cells at late log-phase were harvested by centrifugation. The
76 fatty acid analysis was performed by using the Sherlock Microbial Identification System Version 6.0, with
77 database of TSBA6 (MIDI).

78 To determine the effects of temperature and pH on growth of strain Ok2G^T, cells were cultured in the basal
79 medium supplemented with 0.05% (w/v) yeast extract, and its growth was monitored as optical density
80 measured at 660 nm. The effects of temperature were examined by culturing the strain at 0, 4, 8, 13, 15, 18, 22,
81 25, 28, 32, 35, 37 and 45°C. The effects of pH were examined at 15°C by culturing the strains on the medium
82 with pH initial of 1.6, 2.0, 2.5, 3.0, 3.5, 4.0, 4.5, 5.0, 5.5, 6.0, 6.2, 6.4 and 6.6. Growth inhibition by 0.25 mM
83 acetate was tested at pH 3.6 as described previously [11].

84 Utilization of organic substrates for growth was tested at 25°C with the basal medium without glucose,
85 supplemented with one of the following substrates (numbers without units indicate concentration in mM) as
86 carbon and energy sources: L-arabinose (5), D-fructose (5), D-galactose (5), D-glucose (5), D-mannose (5),
87 D-xylose (5), D-cellobiose (5), D-sucrose (5), glycerol (10), D-mannitol (5), sorbitol (5), ethanol (15), benzyl
88 alcohol (5), methanol (20), phenol (5), sodium acetate (10), sodium benzoate (1), sodium citrate (5), sodium
89 lactate (10), sodium propionate (10), sodium pyruvate (10), tryptone (0.04 %) and yeast extract (0.04 %).

90 Under identical conditions, substrate utilizations of the reference strains mentioned above were also tested for
91 direct comparisons.

92

93 For phylogenetic analysis, the 16S rRNA gene was amplified by PCR using the primer pair 27F and 1492R
94 [12] and then directly sequenced with a BigDye Terminator v3.1 Cycle Sequencing kit (Applied Biosystems).
95 The primers used for sequencing are listed in Table S1. The resulting sequence of strain Ok2G^T was aligned
96 together with the sequences of the related species, by using the ClustalX version 2.1 [13]. All positions with
97 gaps were excluded for further analysis, and 1244 positions were included in the final dataset. The
98 evolutionary distances were computed with Tamura 3-parameter model, using the program *MEGA* version 6.0
99 [14]. Phylogenetic trees were reconstructed with the neighbor-joining and minimum-evolution methods.
100 Bootstrap analysis was performed for 500 replicates.

101

102 Cells of strain Ok2G^T grown at 15°C were non-motile and non-endospore forming rods (1.0–2.8 µm long and
103 0.6–0.8 µm wide) (Fig. S1). On the solid medium, strain Ok2G^T formed domed, round and beige colonies.
104 The cells were weakly positive for catalase and oxidase negative. Gram-staining was negative. DNA G+C
105 content was 62.6 mol%. The major isoprenoid quinone was Q-10.

106 Strain Ok2G^T grew at temperatures between 4 and 35°C, with optimum temperature of 28°C (Table 1). The
107 pH range for growth was pH 3.0 to 6.2, with optimum pH of pH 4.5. As carbon and energy sources to support
108 growth, strain Ok2G^T utilized some sugars and alcohols, as summarized in Table 1 and in the description of
109 the species. The substrate utilizations of the other strains tested in the same medium are also shown in Table 1.

110 As shown in Table 2, the most predominant cellular fatty acid of strain Ok2G^T grown on fructose at 28°C
111 was summed feature 8 (C_{18:1}ω7c and/or C_{18:1}ω6c), accounting for 73.4% of the total. The summed feature 8
112 was also dominant in the fatty acid profiles of all strains tested, but considerable differences in the
113 compositions were observed among the strains (Table 2). The cellular fatty acid profile of strain Ok2G^T was
114 characterized by relatively high content of C_{16:0} 3-OH, in comparison to the other strains cultured under the

115 same conditions. On the other hand, C_{16:0} 2-OH and summed feature 2 (C_{14:0} 3-OH and/or iso C_{16:1} I) were
116 not detected in strain Ok2G^T but detected in the other strains.

117 Among the type strains of species with valid published name, *A. aluminidurans* AL46^T showed the highest
118 16S rRNA gene similarity (96.5 %) to strain Ok2G^T, followed by *A. facilis* PW2^T (96.3 %) and with *A.*
119 *aminolytica* 101^T (95.5 %). In the phylogenetic analysis including these strains, an identical tree topology was
120 obtained by the methods of minimum-evolution and neighbor-joining (Fig. 1). The tree topology indicated that
121 strain Ok2G^T cannot be assigned to any existing species in the genus *Acidocella* (Fig. 1). The analysis also
122 indicated that strain Ok2G^T form a robust cluster with strains isolated from acidic mine drainage-impacted
123 sites in geographically distant localities [6, 7, 8]. This cluster was formed by the strains sharing high sequence
124 similarity (>98%), and may represent a novel species of the genus *Acidocella*.

125 Some differential properties between Ok2G^T and the type strains of *Acidocella* species are shown in Table 1.
126 As a unique feature, strain Ok2G^T can grow at temperatures below the lower limits of the other species. Some
127 differences were also observed in the utilization of substrates for growth (Table 1). In addition, the cellular
128 fatty acid profile of strain Ok2G^T was distinct from those of the strains representing existing species culture
129 under the same conditions (Table 2). In conclusion, strain Ok2G^T should represent a novel species of the
130 genus *Acidocella*, and *Acidocella aquatica* sp. nov. is proposed with the type strain Ok2G^T (= NBRC 112502^T
131 = DSM 104037^T).

132

133 **Description of *Acidocella aquatica* sp. nov.**

134 *Acidocella aquatica* (a.qua'ti.ca. L. fem. adj. *aquatica* aquatic; from freshwater). Aerobic,
135 Gram-stain-negative, non-spore forming and non-motile rods, 1.0–2.8 µm long and 0.6–0.8 µm wide. Growth
136 occurs at 4–35°C with optimum temperature of 28°C and at pH 3.0–6.2 with optimum pH of 4.5. The cells
137 are weakly positive for catalase and oxidase negative. Grows heterotrophically with fructose, glucose, sucrose,
138 mannitol, sorbitol, ethanol, benzyl alcohol, pyruvate, tryptone and yeast extract. Arabinose, galactose,
139 mannose, xylose, cellobiose, glycerol, methanol, phenol, sodium acetate, sodium benzoate, sodium citrate,

sodium lactate, and sodium propionate do not support the growth. DNA G+C content of the type strain is 62.6 mol%. Major cellular fatty acids and isoprenoid quinone are summed feature 8 (C_{18:1}ω7c and/or C_{18:1}ω6c) and Q-10, respectively. The type strain Ok2G^T (=NBRC 112502^T =DSM 104037^T) was isolated from a freshwater lake (Lake Okotanpe) in Japan.
