Estimation of equilibrium of water gas shift reaction (WGSR)

WGSR is written as

Therefore, change in Gibbs free energy at t (K) (ΔG_f^t) can be written as

$$\Delta G_f^t = \Delta H_f^t - t\Delta S_f^t$$

where ΔH_f^t and ΔS_f^t are change in enthalpy and entropy at t , respectively.

By using thermodynamic parameter of each molecule, ΔH_f^t and ΔS_f^t are written as

$$\Delta H_f^t = H_{\text{CO}_2}^t + H_{\text{H}_2\text{O}}^t - H_{\text{CO}}^t - H_{\text{H}_2}^t$$

$$\Delta S_f^t = S_{\text{CO}_2}^t + S_{\text{H}_2\text{O}}^t - S_{\text{CO}}^t - S_{\text{H}_2}^t$$

Each thermodynamic parameter can be calculated by using molar heat capacity at constant pressure

($\overline{C_p}$)

$$H^t = H^{298.15} + \int_{298.15}^t \overline{C_p} dt$$
$$S^t = S^{298.15} + \int_{298.15}^t \frac{1}{t} \overline{C_p} dt$$

Further, $\overline{C_p}$ s of each molecule are known to be related to temperature by following empirical equations. (J. Larminie, A. Dicks, Fuel Cell Systems Explained, second Ed., John Wiley & Sons Ltd, West Sussex, England, 2003.)

$$\text{H}_2\text{O (steam)} \quad \overline{C_p} = 143.05 - 58.040T^{0.25} + 8.2751T^{0.5} - 0.036989T$$

$$\text{H}_2 \quad \overline{C_p} = 56.505 - 22222.6T^{-0.75} + 116500T^{-1} - 560700T^{-1.5}$$

$$\text{CO} \quad \overline{C_p} = 69.145 - 0.022282T^{0.75} - 2007.7T^{-0.5} + 5589.64T^{-0.75}$$

$$\text{CO}_2 \quad \overline{C_p} = -3.7357 + 3.0529T^{0.5} - 0.041034T + 2.4198 \times 10^{-6}T^2$$

According to above relationship, thermodynamic parameters at 443.15 (K) (170 °C) can be calculated as

gases	$H^{298.15}$ /J mol ⁻¹	$H^{443.15}$ /J mol ⁻¹	$S^{298.15}$ /J K ⁻¹ mol ⁻¹	$S^{443.15}$ /J K ⁻¹ mol ⁻¹
H ₂ O(steam)	-241827	-236891	188.83	202.3101
H ₂	0	4218.305	130.59	142.1127
CO	-110529	-106294	197.65	209.2213
CO ₂	-393522	-387711	213.80	229.6046

※ $H^{298.15}$ and $S^{298.15}$ are referenced from ref.

In this results, $\Delta G_f^{443.15}$ can be calculated as -22.66 kJ mol⁻¹. ($\Delta G_f^{443.15}$ for RWGSR is 22.66 kJ mol⁻¹)

Now, when initial partial pressure of H₂ and CO₂ are 6 MPa and 2 MPa, respectively, equilibrium constant (K^t) can be written as

$$K^t = \frac{(2-x)(6-x)}{x^2}$$

where x (MPa) is partial pressure of H₂O and CO at equilibrium.

Simultaneously, equilibrium constant (K^t) is related to ΔG_f^t as follows.

$$\Delta G_f^t = -Rt \ln K^t$$

where R is gas constant. When t and ΔG_f^t are 443.15 K and -22.66 kJ mol⁻¹, x can be calculated as ca. 0.15 MPa, suggesting that ca. 7.5 % of CO₂ will be converted to CO until reaching to equilibrium. Concerning volume of autoclave (40 mL), amount of evolved CO at equilibrium is ca. 2.7 mmol, which is corresponding to TON = 135 in case of SILP-Cl (1.6) (1.0 g of SILP-Cl includes ca. 2.02×10^{-2} mmol of Ru.).

DRIFTS of SILP-Cl(1.6) which was heat treated under various gas conditions.

SILP-Cl (1.6) was heat treated at 170 °C under N₂, H₂ or H₂/CO₂ atmosphere and DRIFTS was measured for each sample. The results are shown in Figure S1.

Figure S1. The results of DRIFTS measurement of SILP-Cl (1.6). (a) before heat treatment, (b) treated under N₂ ($P_{N_2} = 2$ MPa) at 170 °C for 10 h, (c) treated under H₂ ($P_{H_2} = 6$ MPa) at 170 °C for 2 h and (d) treated under CO₂/H₂ ($P_{CO_2}/P_{N_2} = 2$ MPa /6 MPa) at 170 °C for 10 h. Since catalyst is reduced to be Ru metal at high temperature under pure H₂ atmosphere and carbonyl peak in DRIFTS becomes small, time of heat treatment was set at 2 h.

Figure S1 clearly shows shift of CO vibration peaks to lower wavenumber after heat treatment.

After heat treatment under N₂, CO vibration peaks was shown at 2051 cm⁻¹ and 1981 cm⁻¹ (Figure S1 (b)). These peaks can be assigned to [RuCl₃(CO)₂]⁻. After heat treatment under H₂ atmosphere, additional peaks were found at 2023 cm⁻¹ and 1939 cm⁻¹ (Figure S1 (c)). These peaks can be

assigned to $[\text{RuHCl}_2(\text{CO})_2]^-$. Finally, even after heat treatment under CO_2/H_2 mixed gas conditions, peaks are shown at same position to Figure S1 (c) with different intensity.
