Abstract: Topochemical reactions between CaCrO_3 and polyvinylidene difluoride yield the new fluorinated phase $\text{CaCrO}_{2.5}\text{F}_{0.5}$, which was characterized by powder synchrotron X-ray diffraction, X-ray photoemission spectroscopy, and magnetic susceptibility measurements. The reaction proceeds via reduced oxide intermediates, $\text{CaCrO}_{2.67}$ and $\text{CaCrO}_{2.5}$, in which CrO_6 octahedral and CrO_4 tetrahedral layers are stacked in a different manner along the c axis of CaCrO_3 . These two intermediate phases can be selectively synthesized by the carbothermal reduction with $\text{g-C}_3\text{N}_4$. Both CaCrO_3 and $\text{CaCrO}_{2.5}\text{F}_{0.5}$ adopt the same orthorhombic space group, $Pbnm$; however, the fluorinated phase has decreased Cr-O-Cr bond angles as compared to the parent compound in both the ab plane and along the c -direction, which indicates an increased orthorhombic distortion due to the fluorination. While the oxygen vacancies are ordered in both intermediate phases, $\text{CaCrO}_{2.67}$ and $\text{CaCrO}_{2.5}$, a site preference for fluorine in the oxyfluoride phase cannot be confirmed. CaCrO_3 and $\text{CaCrO}_{2.5}\text{F}_{0.5}$ undergo antiferromagnetic phase transitions involving spin canting, where the fluorination causes the transition temperature to increase from 90 K to 110 K, as a result of the competition between the increased octahedral tilting and the enhancement of superexchange interactions involving Cr^{3+} ions in the $\text{CaCrO}_{2.5}\text{F}_{0.5}$ structure.

Introduction:

Recently, the development of topochemical techniques have allowed for the facile synthesis of phases with new anion lattices or metal coordination geometries in oxides, the synthesis of which has been central in solid state chemistry, as it expands our knowledge of structure property relationships.¹ A number of oxygen deficient or oxyfluoride phases have been obtained by treating oxides normally obtained easily by solid state reactions with either a reducing or fluorinating agent.^{2, 3} Topochemical reduction using an alkali/alkaline hydride yields novel oxyhydrides and oxygen-vacancy ordered compounds. For example, $\text{LaSr}_3\text{NiRuO}_4\text{H}_4$ with metal hydride sheets and $A\text{FeO}_2$ ($A = \text{Ca}, \text{Sr}, \text{Ba}$) with square-planar oxides⁴ are obtained from the corresponding oxide phases.⁵⁻⁷ Low-temperature fluorination reactions using fluorine gas, fluoropolymer or a binary metal fluoride also allow for unique anion-lattice modification via the substitution of fluorine for oxygen and/or fluorine insertion,⁸ as exemplified by the synthesis of superconducting $\text{Sr}_2\text{CuO}_2\text{F}_{2+\square}$ from Sr_2CuO_3 .⁹

Applying these topochemical methods to materials obtained from high-pressure synthesis, a ‘hard-soft’ synthetic approach, is under explored and can lead to the exploration of metal coordination environments that aren’t readily accessible at ambient pressures. For example, it is well known the tetravalent chromium cation strongly favors tetrahedral coordination over octahedral coordination and the ionic radius is too small to be incorporated into perovskite structures, although these observations are not without exceptions.¹⁰ Previously, alkaline chromium oxide perovskites such as $A\text{CrO}_3$ ($A = \text{Ca}, \text{Sr}$) have been stabilized under high pressures,^{11, 12} and Arevalo-Lopez and Attfield *et al.* have discovered new oxygen-vacancy ordered phases CaCrO_{3-x} ($x = 0.33, 0.4, 0.5$)^{13, 14} and SrCrO_{3-y} ($y = 0.2, 0.25$),¹⁵ which were synthesized

by reduction of $ACrO_3$ ($A = \text{Ca}, \text{Sr}$) with hydrogen gas. $\text{CaCrO}_{2.5}$ was found to adopt the brownmillerite structure. These oxygen deficient layers depend on the A site cations: vacancies in CaCrO_{3-x} are formed in the (001) plane of the cubic perovskite structure, but vacancies in SrCrO_{3-y} are formed in the (111) plane (Figure 1).

Figure 1. Structures of $ACrO_3$ ($A = \text{Ca}, \text{Sr}$) and their reduced products obtained by reductive reactions carried out with $\text{g-C}_3\text{N}_4$. $\text{CaCrO}_{2.5}$ adopts the brownmillerite structure. Chromium octahedra are shown in green, oxygen atoms in red, and A atoms in blue.

Very recently, our research group reported the topochemical fluorination of SrCrO_3 with polyvinylidene difluoride (PVDF), which involved the formation of $\text{SrCrO}_{2.8}$ as an intermediate oxide.¹⁶ The layers of tetrahedrally coordinated Cr^{4+} in $\text{SrCrO}_{2.8}$ create a pathway for the subsequent fluorine insertion, and the resulting oxyfluoride phase was the cubic $\text{SrCrO}_{2.8}\text{F}_{0.2}$ with fluoride ions randomly distributed in the structure. Furthermore, $\text{SrCrO}_{2.8}$ could be isolated for the first time by topochemical reduction with $\text{g-C}_3\text{N}_4$.¹⁶ It should be noted that the degree of fluorination in SrCrO_3 seems to be restricted by the amount of the oxygen deficiencies in the intermediate phase. Thus, to gain deeper understanding of the fluorination mechanism for SrCrO_3 ,

it is useful to perform chemical substitution in the parent materials and explore the different types of oxygen deficient phases obtained by reduction.

In this study, we report the fluorination and reduction of CaCrO_3 with PVDF and $\text{g-C}_3\text{N}_4$, which revealed stepwise fluorination processes similar to that for SrCrO_3 but different pathways for oxygen removal and fluorine insertion as well as higher degree of fluorination.

Experimental

Synthesis. CaCrO_3 powder was obtained using a multi-anvil high-pressure method previously reported by Weiher *et al.*¹¹ CaCO_3 was heated over night at 1000 °C in air to obtain CaO , which was combined stoichiometrically with CrO_2 (Aldrich) in an Ar filled glovebox and loaded into a Pt capsule. The Pt capsule was loaded into a high-pressure cell and heated at 900 °C under a pressure of 5 GPa for 1 h before quenching to room temperature by turning off the heat before releasing the pressure. The black polycrystalline product, CaCrO_3 , contained a CaCr_2O_4 impurity (13 wt.%) and was fluorinated using PVDF (Aldrich) in molar ratios of 0.1 to 0.5 (PVDF/ CaCrO_3). PVDF and CaCrO_3 were mixed, pelletized, and sealed in a glass tube under vacuum before heating at temperatures of 350, 370, and 400 °C. CaCrO_3 was also reduced using $\text{g-C}_3\text{N}_4$ (synthesized in house) in ratios of 0.25 ($\text{C}_3\text{N}_4/\text{CaCrO}_3$) following a similar procedure.

Structure. The structures of the resulting powders were analyzed by Rietveld refinement using synchrotron X-ray powder diffraction (SXRD) data collected at room temperature using one-dimensional X-ray detectors installed on BL15XU, NIMS beamline at SPring-8 in Japan. The synchrotron radiation X-rays were monochromatized to the wavelength of 0.65298 Å. The samples were loaded in glass capillaries and inner diameter of 0.1mm, and the diffraction data were

recorded in 0.003° increments over the range of $4 \leq 2\theta \leq 60^\circ$. Structure refinements were performed using the Rietveld method with the program RIETAN-FP.¹⁷ X-ray Photoemission spectroscopy (XPS) measurements were performed by using Mg $K\alpha$ X-ray source (JEOL JPS-9010MC). The Fermi level was calibrated using the C1s signal.

Results and Discussion

Synthesis. For both post-synthetic fluorination and reductive reactions, a temperature of 400°C produced better results, although the reactions can be carried out at 350 and 370°C but the reactions did not reach completion at these temperatures. The reactions of CaCrO_3 with PVDF at different ratios show a stepwise fluorination of CaCrO_3 , where CaCrO_3 is first reduced to $\text{CaCrO}_{2.67}$ and $\text{CaCrO}_{2.5}$, before the fluorinated phase forms (see Figure 2). At ratios of 0.1 and 0.2 (PVDF/ CaCrO_3) $\text{CaCrO}_{2.67}$ and $\text{CaCrO}_{2.5}$ are formed, and these phases disappear as the fluorinated phase, $\text{CaCrO}_{3-x}\text{F}_x$, begins to form at a ratio of 0.3 (PVDF/ CaCrO_3). These behaviors suggest that fluorine is inserted into the tetrahedral layers of $\text{CaCrO}_{2.5}$. The fluorinated phase obtained at 0.5 (PVDF/ CaCrO_3) can be assigned to an orthorhombic cell with $a = 5.34098(9) \text{ \AA}$, $b = 5.40324(9) \text{ \AA}$, and $c = 7.53180(10) \text{ \AA}$. Low-temperature reduction using g- C_3N_4 was also examined on CaCrO_3 , which resulted in the successful isolation of $\text{CaCrO}_{2.5}$ and $\text{CaCrO}_{2.67}$ under controlled reaction temperatures, although a few uncharacterized peaks, which disappear at higher temperatures, were detected in $\text{CaCrO}_{2.67}$ as indicated in the right panel of Fig. 2. We notice that both the fluorination and reduction of CaCrO_3 causes peak broadening, which is probably due to a reduced crystallinity through the topochemical reactions.

Figure 2. SXRD patterns of the products obtained by reactions of CaCrO_3 with PVDF or $\text{g-C}_3\text{N}_4$. CaCrO_3 is fluorinated via two oxygen deficient phases, i.e. $\text{CaCrO}_{2.67}$ and $\text{CaCrO}_{2.5}$. These reduced phases can be isolated by controlling the reaction temperature with $\text{g-C}_3\text{N}_4$.

Structure. Figure 3 shows the result of Rietveld refinement against the PXRD data collected from the product obtained by the reaction of CaCrO_3 with PVDF at 400 °C. Even after the fluorination reaction, the structure retained the orthorhombic space group $Pbnm$, but the lattice constants increased by 0.98, 1.60, and 0.60% along a , b , and c directions, respectively. The variation in volume ($\Delta V/V$) is 3.2%, which is larger than the volume change between SrCrO_3 and $\text{SrCrO}_{2.8}\text{F}_{0.2}$ (2.5%) but smaller than that between SrFeO_3 and $\text{SrFeO}_{2.5}\text{F}_{0.5}$ (8.2%).^{15, 16} No additional peaks associated with O/F anion ordering were detected. For structural refinement of the oxyfluoride phase, the crystal structure of CaCrO_3 was used as a starting model. No attempt was made to distinguish oxide and fluoride ions because of their similar X-ray scattering factors. CaCr_2O_4 and CaF_2 were also added to the refinement as secondary phases. The refinement readily converged well to $R_{\text{wp}} = 2.01\%$ and $R_{\text{B}} = 3.73\%$. No anion-site deficiencies were found within the error margin, indicating that the oxygen vacant sites in $\text{CaCrO}_{2.5}$ were completely filled with fluoride ions. Thus, the expected chemical composition is $\text{CaCrO}_{2.5}\text{F}_{0.5}$, implying higher degree of

fluorination than that for SrCrO_3 .¹⁶ Rietveld refinements were performed on PXRD data collected on the parent structure, CaCrO_3 , and the reduced structure, $\text{CaCrO}_{2.5}$, and are shown in Figures S1 and S2, although there are no new results considering both structures have previously been thoroughly characterized.^{14,11,18} The refined atomic coordinates for $\text{CaCrO}_{2.5}\text{F}_{0.5}$, CaCrO_3 , and $\text{CaCrO}_{2.5}$ are shown in Tables S1-3.

Figure 3. Rietveld refinement against the PXRD data collected from the fluorinated product at room temperature. The observed (red crosses), calculated (black solid line), and difference (blue solid line) plots are shown. The vertical lines represent the fluorinated phase (81%), CaF_2 (12%), and CaCr_2O_4 (7%) from top to bottom. The inset shows an enlarged plot in a high 2θ region.

We investigated the change in oxidation state of the chromium ions due to the fluorination of CaCrO_3 by XPS measurements. Figure 4 shows the Cr $2p$ spectra collected from CaCrO_3 and its fluorinated phase. The Cr $2p^{3/2}$ spectrum of CaCrO_3 is decomposed into three components which could be assigned as Cr^{3+} , Cr^{4+} , and Cr^{6+} with binding energies of 576.38, 578.96, and 582.35 eV, respectively.¹⁹ The trivalent and tetravalent chromium should be derived from CaCr_2O_4 and CaCrO_3 , respectively. The atomic ratio of Cr^{3+} to Cr^{4+} estimated from the spectral area is 0.15:0.80, which agrees well with that obtained from the Rietveld analysis (0.17:0.83). The Cr^{6+} species, which were not detected by the SXRD pattern, should be attributed to surface defects. For the oxyfluoride phase, the Cr $2p^{3/2}$ spectrum can be decomposed into Cr^{3+} and Cr^{4+} species in an

atomic ratio of 0.40:0.60. The increase in the Cr^{3+} component is consistent with O-to-F substitution in CaCrO_3 . However, the atomic ratio of Cr^{3+} to Cr^{4+} determined by XPS (0.40:0.60) deviates from that estimated from the PXRD analysis (0.50:0.50) assuming the oxyfluoride phase as $\text{CaCrO}_{2.5}\text{F}_{0.5}$. This discrepancy is likely due to the low signal-to-noise ratio caused by residual C-F species from the fluorinating agent, as seen from the wide-scan spectra in Figure S3.

Figure 4. Cr $2p$ core level photoelectron spectra collected from CaCrO_3 and its fluorinated phase at 300 K. The bold grey and dashed black lines represent the fitting curves and the Shirley background, respectively. The green, orange, and brown solid lines correspond to Cr^{3+} , Cr^{4+} and Cr^{6+} components.

The structure of CaCrO_3 is well studied and adopts the ABO_3 perovskite structure with an orthorhombic distortion due to the small size of the Ca^{2+} ion,^{18, 20} as compared to the cubic SrCrO_3 , and crystallizes in the $Pbnm$ space group with lattice parameters $a = 5.28912(1)$ Å, $b = 5.31796(1)$ Å, and $c = 7.48677(1)$ Å. The oxygen vacancies are ordered in $\text{CaCrO}_{2.5}$ and $\text{CaCrO}_{2.67}$, creating layers of Cr octahedra and tetrahedra (Figure 5). In $\text{CaCrO}_{2.67}$, the tetrahedral layer occurs every third layer, while in $\text{CaCrO}_{2.5}$, which adopts the brownmillerite structure, it occurs every other layer. The relationship of the octahedral layers to the tetrahedral layers can be understood as the removal of every other infinite chain of oxygen atoms as illustrated in Figure 5. This reduces the coordination of Cr from 6 to 4, and as a result the Cr-O-Cr bond which is nearly linear in the

octahedral layers contracts to form the approximately 109° bond angle found in tetrahedral coordination environments.

Rietveld refinement against the SXRD data of $\text{CaCrO}_{2.5}\text{F}_{0.5}$ revealed all of the anion sites in the ABO_3 structure were fully occupied upon fluorination and $\text{CaCrO}_{2.5}\text{F}_{0.5}$ adopted the same space group of the parent compound. The structure symmetry allows anions to occupy two unique sites, namely the sites on the ab plane ($X1$) and along the c axis ($X2$). Thus, the existence of a selective fluorine distribution over the anion sites cannot be ruled out. To examine the possible anion ordering of O/F ions, bond-valence-sum (BVS) calculations were carried out on the assumption of three types of fluorine distribution, namely, on $X1$, $X2$, or both sites. The BVS values for all atoms are summarized in Table S4. Unfortunately, we could not conclude any types of anion ordering: the BVS values for $X1$ and $X2$ sites as well as Ca and Cr sites were consistent with the assumed fluorine distribution patterns.

Figure 6 shows a comparison between the refined crystal structures of CaCrO_3 and $\text{CaCrO}_{2.5}\text{F}_{0.5}$. Hereafter, the full anion disordered model is employed to discuss the structure and properties of the oxyfluoride phase, since no selective fluorine distribution was observed. All the Cr-F/O bond lengths are increased from 1.9002(4), 1.911(1), and 1.912(1) Å to 1.935(1), 1.960(4), and 1.919(4) Å (see Figure 6). These behaviors are consistent with the increased $\text{Cr}^{3+}/\text{Cr}^{4+}$ via the substitution of fluorine for oxygen. The oxyfluoride structure also contains tightened Cr-O/F-Cr bond angles of 156.6(2) and 153.3(3)° as compared to 157.70(8) and 160.13(13)° in the parent structure. A higher degree of the octahedral tilting in the fluorinated perovskite can be accounted for by considering Goldschmidt's tolerance factor (t), which is expressed as $t = (r_A + r_X) / \sqrt{2}(r_B + r_X)$.^{21, 22} The r_A , r_B , and r_X are the Shannon's ionic radii of A -site cation, B -site cation, and X -site anion.²² The calculated t factor of $\text{CaCrO}_{2.5}\text{F}_{0.5}$ is 0.979, lower than more ideal value of CaCrO_3 ($t = 0.994$).

Although no examples of $B-O-B$ bond angle compression upon fluorinating could be found for chromium oxides, $\text{LaSrCoFeO}_5\text{F}$ contains tightened $(\text{Co/Fe})-(\text{O/F})-(\text{Co/Fe})$ bond angles as compared to the oxygen-stoichiometric oxide LaSrCoFeO_6 , both of which adopt the trigonal space group $R\bar{3}c$.²³ $\text{La}_{0.5}\text{Sr}_{0.5}\text{FeO}_{2.5}\text{F}_{0.5}$, which crystallizes in the lower symmetry $Pnma$ as compared to the oxide which adopts the $R\bar{3}c$ space group, also exhibits similar changes in local coordination around the metal center where the Fe-O-Fe bond angles contract from $167.0(3)$ to $163.39(11)$ and $159.68(13)$ and the Fe-O bond distances increase from $1.9567(6)$ to $1.996(4)$, $1.9996(6)$, and $1.986(4)$, upon fluorination.²⁴

Figure 5. Structures of CaCrO_3 , $\text{CaCrO}_{2.5}$, $\text{CaCrO}_{2.67}$, and $\text{CaCrO}_{3-x}\text{F}_x$ showing the sequences of octahedral and tetrahedral layers as a result of oxygen vacancies where chromium octahedra are shown in green, oxygen atoms in red, and calcium atoms in blue.

Figure 6: Detailed view of chromium coordination environments in CaCrO_3 and $\text{CaCrO}_{3-x}\text{F}_x$ where the Cr atoms are shown in green, oxygen atoms in red, and the calcium atoms in white.

Reaction pathway. CaCrO_3 exhibited stepwise fluorination processes as observed in SrCrO_3 .¹⁶ However, the important differences between the fluorination mechanisms of CaCrO_3 and SrCrO_3 are as follows, (1) the degree of fluorination for CaCrO_3 is higher than that for SrCrO_3 , (2) the formation of two intermediate oxide phases of $x = 0.33$ and 0.5 are involved, and (3) the plane where oxygen removal and fluorine insertion occurs is (001) for CaCrO_3 but (111) for SrCrO_3 . It is apparent that the larger amount of fluorine atoms inserted into CaCrO_3 is attributable not only to its deoxidation capacity but also the reducing power of PVDF. Indeed, the first reduced phase $\text{CaCrO}_{2.67}$ is subsequently reduced to $\text{CaCrO}_{2.5}$ prior to the fluorination, whereas for the fluorination of SrCrO_3 the first reduced phase $\text{SrCrO}_{2.8}$ is not further reduced to $\text{SrCrO}_{2.75}$ but directly fluorinated to $\text{SrCrO}_{2.8}\text{F}_{0.2}$. The pathway of the oxygen removal and fluorine insertion for CaCrO_3 , which is different from those for SrCrO_3 , also play an important role in the formation of the highly fluorinated phase $\text{CaCrO}_{2.5}\text{F}_{0.5}$. The fluorine insertion mechanism remains an open question. If fluorine atoms simply occupy the oxygen vacant sites, a partial O/F order on the X1 sites is realized. In contrast, fluorine insertion involving migration of apical oxygen, which was observed for layered perovskite compounds,^{9, 25} would result in a partial anion order on the X2 sites or the full anion disorder. Mitra et al. investigated the oxygen diffusion pathways in

brownmillerite $\text{SrCoO}_{2.5}$ by first-principle calculations, and found that the one-dimensional-ordered oxygen vacant channels in the CoO_4 tetrahedral layers provide the easiest diffusion pathway compared with the directions perpendicular to the vacant channels.²⁵ Based on this study, it is likely that fluorine also migrates and resides in the CrO_4 tetrahedral layers. Similar to the observed O/F disorder in $\text{SrCrO}_{2.8}\text{F}_{0.2}$, the oxygen-deficiency ordered structures do not influence the fluorine sites, perhaps due to the transformation of the Cr coordination from tetrahedron to octahedron which causes the rearrangement of the fluorine atom positions. Similar fluorine migration during fluorination reaction is observed in related perovskite compounds.^{9, 26, 27}

Magnetism. Figure 7 shows the temperature dependence of the magnetic susceptibility χ ($= M/H$) of CaCrO_3 , $\text{CaCrO}_{2.5}$, and $\text{CaCrO}_{2.5}\text{F}_{0.5}$, measured under zero-field-cooled (ZFC) and field-cooled (FC) conditions in the temperature range between 5 and 300 K. Anomalies in the magnetic susceptibility of the samples, or the inverse, from the magnetic impurity, CaCr_2O_4 , with features at 100 K and 21 K,²⁸ were not observed indicating that CaCr_2O_4 did not significantly impact the susceptibility data. The $\chi(T)$ of CaCrO_3 exhibited a sudden increase at $T_N = 90$ K followed by a divergence between ZFC and FC data. These behaviors can be accounted for by a canted antiferromagnetism.¹⁸ The weak temperature dependence above T_N , which does not obey the Curie-Weiss law, is consistent with the metallic state unambiguously characterized by spectroscopic techniques.^{20, 29} For $\text{CaCrO}_{2.5}$, a small cusp associated with an antiferromagnetic ordering was observed at around 240 K in the ZFC data. The T_N value is close to that determined by the neutron diffraction analysis in Attfield *et al.*¹⁴ The small anomaly in the susceptibility at T_N is probably due to the decrease in crystallinity during the reductive reaction. In contrast to $\text{CaCrO}_{2.5}$, the $\chi(T)$ of $\text{CaCrO}_{2.5}\text{F}_{0.5}$ is similar to that of CaCrO_3 : an antiferromagnetic phase

transition involving spin canting was observed at 110 K. The moderate increase in $\chi(T)$ below T_N suggests decreased spin canting angles between Cr ions. It should be noted the high temperature data above T_N cannot be described again by the Curie-Weiss law, although it is somewhat more dependent on temperature than that of CaCrO_3 . In fact, the Curie-Weiss fit gave the Curie constant $C = 4.17(1)$ (emu K)/mol, which is unphysically large compared to the value expected from localized magnetic moments of Cr(III) with $S = 3/2$ and Cr(IV) with $S = 1$. This behavior suggests that the oxyfluoride has a metallic state like CaCrO_3 or insulating state located near the border between metallic and insulating phases. Unfortunately, even the cold-pressed sample after fluorination was so fragile that electrical measurements could not be performed. In light of the fact that CaCrO_3 resides near the crossover regime from itinerant to localized electron system,¹⁸ the O-to-F substitution involving a decrease in the Cr-O-Cr tilt angles and lowered pd hybridization via more electronegative fluoride would shift the chromium perovskite to an insulating phase. Similar enhanced Pauli paramagnetic behaviors are observed in early $3d$ -transition metal insulators such as LaTiO_3 and LaVO_3 ,^{30, 31} which are assumed to be near the metal-insulator transition.

The impact of fluorination on the magnetism greatly differs between CaCrO_3 and SrCrO_3 .¹⁶ In SrCrO_3 showing a Pauli paramagnetic behavior, replacement of 6.7% of oxygen sites with fluorine induces an antiferromagnetic ordered state with $T_N = 230$ K. In contrast, the fluorination of CaCrO_3 increased the magnetic ordering temperature by only 20 K despite the substitution of 16.7% oxygen for fluorine. The difference can be rationalized by considering variations in Cr-(O/F)-Cr bond angles and the oxidation number of Cr ions. In $\text{SrCrO}_{2.8}\text{F}_{0.2}$ with a cubic structure, the Cr-(O/F)-Cr bond angles are 180° , which maximizes the superexchange interactions between Cr ions. Moreover, the presence of Cr^{3+} ions via the fluorination insertion contributes to the enhancement of magnetic interactions. As a result, the high Néel ordering temperature is obtained. In

$\text{CaCrO}_{2.5}\text{F}_{0.5}$, however, $\text{Cr}-(\text{O}/\text{F})-\text{Cr}$ bond angles both along the c axis and on the ab plane become smaller via fluorination, which weakens the nearest neighbor interactions. Thus, the moderate increase in T_N observed in $\text{CaCrO}_{2.5}\text{F}_{0.5}$ should result from a competition between the increased octahedral tilting and the enhancement of superexchange interactions involving Cr^{3+} ions.

Figure 7. Temperature dependence of the magnetic susceptibility of CaCrO_3 , $\text{CaCrO}_{2.5}$, and $\text{CaCrO}_{2.5}\text{F}_{0.5}$, measured under zero field cooled and field cooled conditions. The insets highlight anomalies associated with the magnetic phase transitions.

Conclusion

In this study, the new fluorinated phase, $\text{CaCrO}_{2.5}\text{F}_{0.5}$, was isolated by reacting CaCrO_3 with PVDF at 400 °C. This reaction proceeds via reduced oxide intermediate phases $\text{CaCrO}_{2.67}$ and $\text{CaCrO}_{2.5}$, which can be obtained by reacting CaCrO_3 with $g\text{-C}_3\text{N}_4$. The degree of fluorination for CaCrO_3 is higher than that for SrCrO_3 , which is attributed to the deoxidation capacity that is more easily maximized by PVDF. The structure of $\text{CaCrO}_{2.5}\text{F}_{0.5}$ was characterized by synchrotron powder diffraction and adopts the same structure as CaCrO_3 with slightly larger lattice parameters with no

detectable O/F ordering. This structure is supported by the XPS results which reveal $\text{Cr}^{3+}/\text{Cr}^{4+}$ ratios close to the expected value of 0.5/0.5 for the proposed $\text{CaCrO}_{2.5}\text{F}_{0.5}$ structure based on full anion site occupancy. Magnetic measurements reveal that the fluorinated product has an increased spin-canted antiferromagnetic phase transition temperature as compared to CaCrO_3 , which is due to the competition between the increased octahedral tilting and the enhancement of superexchange interactions involving Cr^{3+} ions in the $\text{CaCrO}_{2.5}\text{F}_{0.5}$ structure.

Supporting Information

The supporting information contains plots for the Rietveld refinements and tables atomic positions of CaCrO_3 and $\text{CaCrO}_{2.5}$, a wide scan XPS spectra for CaCrO_3 and $\text{CaCrO}_{2.5}\text{F}_{0.5}$, and inverse magnetic susceptibility plots for all three compounds.
